1703. Re: An AB2 amplifier modulated.

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-06 23:32:14 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <b48lpu$i66$1@knossos.btinternet.com>
Source record: 37105

Plate modulation relies on the principle of class-C, grounded cathode
operation with the tube being hard driven into saturation throughout the
modulating cycle.

For low distortion modulation the plate current should be directly
proportional to plate voltage as the plate voltage swings between a low
value and almost twice the unmodulated DC value.

Typical operating angles for plate modulation are around 100 to 130 degrees.
Class-AB2 linear-amplifier operation is around 190 degrees.

To improve modulating linearity and reduce plate dissipation the screen grid
is operated at a lower than normal DC voltage and the plate RF load has a
higher value than usual.

The behaviour of plate-modulated tetrodes and pentodes can be analysed with
program TETRODE1. Setup a tuned amplifier and vary (modulate) DC plate
voltage from the keyboard while observing plate RF volts and ouput power.

Download program TETRODE1 from website below in a few seconds and run
immediately.

I just looked over the 'Max' site. It is very nice and I think cheap for fiberglass. I saw a single 20 spreader for 19.95. That totals 160 bux. Plus shipping. If you order from one of the 'major' quad companies they wanted 320 bucks.

Think I found my spreaders.

Thanks guys.

>not sure what you mean by "huff-and-puff", but for sure, a
>frequency-locked-loop (what I suspect you mean by h-a-p) is not the
>same as a phase locked loop.

Well, it is and isn't. :-) The "huff and puffs" (Brit term, I believe) is a _stabilizer_ for a normally-manual-tuning variable oscillator. The basic "huff and puff" holds frequency within a relatively narrow frequency range but specific frequency indication is not part of the basic concept (although it could be added easily).

Hans Summers nice website has a number of articles on the "huff and puffs" available for downloading...including his own application. See his previous message in here.

Stabilizers are in a sort of "interim" category, one that bridges only-manually-variable continuously-tuned oscillators to keeping that quality but allowing rather good stabilization at small increments of tuning. Since "huff and puffs" don't involve the artifacts and aliases of DDS (they are essentially as noise-free, artifact-free as simple LC oscillators), they are easier to apply in homebrew projects. They don't need wide-range or high-resolution spectrum analysis to check them out.

>And not all PLLs are created equal, for
>sure. If you run the phase comparator of the PLL at a very low
>frequency so you get very close spacing of available frequencies, then
>the PLL won't be able to take out phase noise at even moderate offsets
>from the carrier.

As an aside, I will challenge that "phase noise" charge. :-)

If one is involved in CDMA, QPSK, M-ary Whatever Alphabets, phase noise will affect signal quality and BER and stomach acid quantities. Today's industrial-strength datasheets

emphasize phase noise specifications because that is what the BIG-volume IC purchasers are concerned about. Given that the USA has roughly 100 million cellular telephones in use now, that scope and size and market profit potential is going to drive what is important in certain datasheets.

Few radio amateurs are into cellular telephony applications, BER values, etc., etc. Frequency source phase noise will affect certain FM applications in amateur work, now done at VHF or above. It might, but not absolutely, be of some technical importance at very narrow bandwidth moonbouce applications using CW on 6 meters.

A single loop PLL will work just fine at small increments, say 10 Hz. Trouble of a different sort arises on trying to rapidly tune quickly. The control loop time constants must be down in the 0.3 second ranges for 10 Hz control increments and the divider chain has to be longer by the inverse of the frequency increment. One can build a 1 Hz increment PLL and not worry overly much on phase noise. That is fine for a very fixed frequency control application.

Multiple-loop PLLs get around the problem by having each multiple controlled at much higher increments, say 1 KHz as is common in the Icom family of 1980s-to-mid-1990s. Those loops "nest" by division-by-ten and mixing with next-higher loops. Manual (or computer-controlled) tuning is much faster, no noticeable lag in knob-twiddling fast or slow, yet the controlled increments are very small. Those are complex and must be chosen carefully to avoid intermods from certain harmonic products, noise build-up from many loops, etc.

The Direct Digital Synthesis group of controlled sources takes in most of the "fractional-N" types and the "NCOs" or Numerically Controlled Oscillators (a technical misnomer but a catchy trade term). Very little hardware there compared to mulitple-loop PLLs and one can, definitely, control quickly to very small increments of frequency over a relatively wide tuned frequency span. While it is relatively simple in number of parts, certain DDS design constants must be very strict to avoid aliasing and weird artifacts not readily found in PLLs and certainly not in simple L-C frequency sources. DDSs are not intuitive in operation, absolutely need some kind of microprocessor assistance (usually on board DDS ICs). Once a DDS subsystem has been worked out in the lab, it is a nice profit-maker for a fast-control, small-increment frequency source manufacturer.

>So...to keep things simple but good performance, make a VFO oscillator
>with inherently good phase noise, give it voltage control that can
>take out whatever long-term drift you anticipate (that is, a very

>logic (more divider stages) than an FLL, it shouldn't be hard to fit
>one into a single medium-size CPLD, or perhaps a small microcontroller
>with a tiny bit of external logic.

An ordinary L-C continuously-variable VFO shouldn't be counted out. In the old Heathkit "SB" series of kits, I measured (a couple decades ago) the frequency stability at 29 MHz of less than 125 PPM overall over a cold-soak at 58 F to an hours-later hot ambient of 92 F. The VFO, common in that line at 5.5 to 5.0 MHz, drifted less than 250 PPM by itself, locked to 5.35 MHz.* The second harmonic of 5.35 MHz falls at 10.7 MHz, the standard IF for old FM broadcast receivers...which can be used to to measure ALL of the incidental FM with some care and calibration. Nothing was heard/seen that seemed worthwhile to note on any incidental FM at that time. No PLL, no DDS, just a crystal oscillator and the L-C tuning VFO, all in a kit and not designed in Iowa. That VFO was a sub-contracted assembly quite frequency-linear in tuning.

It is quite possible to achieve stability in frequency and a very minimum of "noise" with simple L-C oscillator frequency sources, but the designer has to WORK to achieve that.

Len Anderson
retired (from regular hours) electronic engineer person

* 125 PPM = 3.6 KHz at 29 MHz; 250 PPM = 1.3 KHz at 5.35 MHz. Two separate measurements, closed circuit. First measured transceiver output frequency stability at 29 MHz. Second measured just the VFO output through a pickup loop and amplified in a 20 db lab amplifier, VFO not disconnected.

Tom,

I agree with you that Gurus are of MUCH value. Internet "gurus" are sometimes hostile and of questionable knowledge, I've found. I do have one guru friend. His knowledge, especially practical "get it working" knowledge is wide and vast, but he stops short of any spice or mathematical treatments of circuits. I need another guru or two to fill that void.

I wish there was a guru network or something to hook you up with local elmers who are willing to spend time with novice experimenters. Does such a thing exist? I know there are organizations of retired business professionals who lend their free time and advice to people who want to start their own businesses, so it can't be that hard to achieve.

If it's for _speaker_ cable as the subject line suggests, I'd say that ordinary zip cord would be fine. Maybe $0.10 per foot (+/-, depending on gauge, etc.) at a local hardware store? YMMV and you're bound to get other opinions. What that web site brought up for me was balanced, shilded mic cable, and if it's good quality cable, a buck a foot for small quantities doesn't sound outrageous to me. OTOH, if you don't need the flexibility and a rugged jacket on the cable, I'm sure you can find cheaper. What are the important characteristics in your application?

Cheers,
Tom

Greetings Tom,

What I'm wanting to do is run approx 20' of cable for an amplified speaker (12 watts). Of course the speaker would require it's
audio input (two wires) and it needs 12v DC (two wires), total of four wires.

I am not sure if I'd need shielded cable or not. My inclination was to use shielded to help insure no RF got into the audio. The
HeilWire concept looks great but I'm open to suggestions from those who know as to what's good wire to use and if RF should be a
concern with a long speaker extension!

Vic

Of course.

>If I had one "lying around
> gathering dust," why would I sell it to you for significantly less
> than what it would fetch on Ebay? So--there may indeed be a reason:
> for example, because I thought you had talent that would be worth
> contributing to, to develop.

For your hatred of Ebay and hope for the next generation of radio designers who will actually use your 8568b and not resell it at 100% profit.

I got an SP-600 advertising the exact same way. A guy (Hi Dick!) in the next town had a MINT SP-600 that was literally gathering dust. He read my post and emailed me. He knew I'd use it, and I do, every night (usually for dusk-enhancement/greyline and sometimes dawn-enhancement).

I listen to the SP-600 more than the Drake R8. Better filters and sound. I usually use the R8 to check which freq the Sp-600 is really tuned to. But I need the R8 because hauling the SP-600 for a car mini-DXpedition to Rockport (on the sea shore) is a pain. :-) And the R-390 may be better, but changing freqs is such a pain (literally, wrist pain). So I scan with the SP-600, and zoom in on the r-390, if need be. And yes, I could tap the Sp-600 LO and use my freq counter, but I don't like messing with antiques that are in great shape.

BIG QUESTION:
I want to know why my R-390 non-A can hear stuff that my Drake R8 can't, given the R-390 non-A came out in the early 1950's, and the R8 in the early 1990's.

>Do you really "need" one for your home
> workbench?

It would be the rock of my test equipment collection, against which I would check everything else. I've got the 7603 scope, several sig generators (Tek and Marconi), etc. Now I check everything by

zero-beating everything against 10 MHz WWV on the scope.

>Or could you use one at, say, a nearby community college,
> or on the bench of some Elmer?

I live about a mile from Tufts, where I attended and taught as a TA. They had spec analyzers of 400 kHz max freq range. I need higher (see below).

If an elmer wants to lend me one or let me go to his/her place, that would be great. Anyone step to the plate?

>What if someone could loan or rent one
> to you?

Loan would be great. Rent might be tough due to employment status. Hence the "extra time" to devote to radio design at home.

> And...what upper frequency _do_ you want to cover?

I'd like to cover at least upto 120 MHz, which is for the DDS running at 120 MHz, then divide by 4, for my top HF freq of 30 MHz.

>What frequency
> accuracy do you need? What minimum resolution bandwidth?

As much as I can get. I have to check for spurs everywhere.

I'm following KE9OA'a and Youngblood's work closely.

I was already in a group making our own receivers at a military radio place near Boston. One guy's mantra said "preselectors are cheating", regarding dynamic range and strong signal overloading. That's the caliber of the work. But they made mil-radios that were onesies and twosies used for very special purposes. And allegedly did better than the r-390 (and r-1051/r-2368?) at dynamic range and strong signal overload, but incredibly expensive. Unfortunately, the company went under. The radio-making-group fell apart when one started talking money for the radios we would make for the commercial market. I'm more of a GNU guy (see GNUradio). Pay for hardware, and software is free and fun.

>What
> display capability? Could you do what you need with a general-purpose
> non-synthesized wideband analyzer, combined with something that could
> get you high-res narrow spans? (Do you already have a good
> generator?)

I'd need to sweep near zero to at least 200 MHz for spurs etc in a possible design (again, see ke9oa and Youngblood). Put it on peak-hold, and let it sit there for hours or days, while changing freqs, voltages, etc. I want high-res BW throughout at least 200 MHz. I want the LO phase noise as low as I can get it (crystal-like, or at least like AOR-7030), to minimize IMD. If there's another method, let

me know. If any high frequency junk gets into the DSP and aliases, I'm screwed.

This is probably more than you wanted to know, but shows you why I'd like a HP 8568B. We used the HP 8568b (and HP 8569, higher freq brother) at the mil-radio place, which had at least 5 of them. Don't know where they went when the company went under, dammit.

Any other comments on how to attack this problem would be greatly appreciated.

Thanks,
Paul

In some cases, the slotted plate is an aperature coupling/isolating
device which is only partialy coupling input/output energy. The reason
for this reduction and seemingly inefficeint device is that gunn oscillators
pull in frequency like crazy with differant variations of loading.

In some cases the slotted device you see may be a bandpass type of filter
to reduce interferance.

Best luck, (Radarman)

If your DC isn't clean, you could have some noise issues with the DC
wiring so close to your audio wiring.

OOOPPPPSSSS..... When I acquired these, I took a quick glance at them. They looked like crystals, so rather than investigate further - even though the markings were a bit weird to me to be crystals, I threw them in a box marked crystals and left them go at that. MY ERROR....

Thanks to a couple people who pointed this out and corrected me as to the manufacturer of these and their lines. Personally, I've never heard of the company.

Anyhow, since I stand corrected these are still up for sale, if any one needs any. Obviously the price will be different too! If interested, make a decent offer and I'll get back to you. Please reply direct as I'm not always able to receive the news groups.

One more reason among many lately for me to get my glasses changed!!!!!!!!

Thanks again fellas!

I am looking for both transistors. I bought TS700S from honest(?) ham
who said the radio worked perfect and found out that both driver and
final is dead.And this honest ham accused me that I destroyed it. I
only connected to dummy load and pressed the mic see if it worked. hi
hi
Can't seem to find the exact part or replacement. I think RF parts
sells them but asking arm and leg.
Anybody has these parts for reasonable price?
Thanks for reading.

Heh...I'm not wanting to start a flambe' a la newsgroup, but
I've had to do a lot of searching for those easy-to-find,
not terribly expensive 1 PPM or better references. Closest I
can come in reasonable prices for a new unit is an
ECS VC-TXO-39SM at 10 MHz in an SMD package, costing
$15.12 in singles from Digi-Key (in the web catalog, not in
newsprint mailed version). That's a voltage-controlled crystal
oscillator which is intended for a replacement frequency
counter as the timebase master oscillator. That ECS model
number family has several fixed frequencies from 10 to 19 MHz.

>"Solid-State Design for the Radio Amateur" has a circuit for a
>low-phase-noise LC oscillator that should do fine for the VCO, so
>there's not much hobby time involved in that. And of course, if
>there's an available reference design for the PLL part, that speeds
>things up a lot, too.

Quite true, no argument, but there are mitigating conditions to
everyone's homebrew project. I would judge a "huff and puff"
system to least disturb an existing VFO/VCO yet provide a
good stabilization of its frequency. It isn't optimum. Optimum
criteria have to be defined by the homebrewer.

A "huff and puff" system automatically creates FM/PM "noise"
in that basic method. But, that "noise" can easily be tolerated
in-use either as Tx or Rx. It would be terrible for a high-speed
data communication system using Costas loops and I-Q demod
or mod. Works fine for CW or DC SSB AM on MF-HF bands.

For small increments of tuning over a relatively large tuning span,
a DDS is hard to beat for a least-parts subsystem and it can
yield excellent stability on each setting. On the other hand it is
a more complex task to control the divisors and fractions
thereof and to find the least spur/artifact/alias/whatever conditions
to not mess up an Rx or Tx. Analog Devices has some nice
Appnotes on that subject on their website. Once that is done,
each of tens of thousands of frequencies will be as stable as the
reference frequency source.

A composite of mixing large-increment PLL frequencies with a
fixed-range, stabilized VFO can generate frequencies on all the
MF-HF bands, either for Tx or Rx. For a new project, I'd judge
that to have the least design-and-build overall work...without
having to spend all the test time with the VFO.

Single-loop PLLs are basically simple, the R-C loop filter
equations are out there. At least one LSI, the Motorola
MC145151, is still sold by Jameco and contains the PLL

oscillator, divider, phase-comparator, and reference frequency input (choice of crystal reference oscillator in-board or out-board). Add the VFO and a mixer, perhaps an L-C filter(s), and a multiband tunable frequency source is done.

There's a lot of options to choose from...

1721. Re: looking for a HP 8568B spectrum analyzer

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-07 07:22:02 UTC
From: Pete KE9OA <n.gianakopoulos@worldnet.att.net>
Message-ID: <uMX9a.4445$Oz1.346292@bgtnsc05-news.ops.worldnet.att.net>
Source record: 37123

One way around this problem is with a low frequency analyzer, such as the
3582, using a clean signal source with a mixer to translate the frequency
down. The HP 70000 Phase Noise test system that we used at Rockwell-Collins
used this setup. A 3585 was used out to a 40MHz offset, while the 3582
would do the close-in stuff. The system could measure down to -154dBc. We
used to use this system for characterizing OCXOs when I was working in the
Synthesizer Group. I know that it is cumbersome, but it could work, if you
have a clean signal generator to use as an LO source. I think one of the
best generators available was the HP 8642 series. They used that modulated
fractional N divider
(MFD, Sigma-Delta Modulation), ending up with a phase noise spec
of -153dBc.
Sorry about the rambling! A 3580 would do the trick in your case, along
with a Mini-Circuits SRA-3 mixer.

Pete

Hi Hans (nice Swedish name),
Are you seriously going to pay these prices? If you want a 100% replacement transformer then Ok, but it is still a lot ot pay. I would be tempted to:

1. Get a 500W 120/220v autotransformer and rewind it/add windings (the primary is already there).
2. Use more than one transformer (230 to 230v isolation + 6.3v etc.)
3. Rob one from another bit of kit.

If I had 50+ bucks to spare I would have a much better home for it that a US transformer manufacturers profit margin.

BR SM0VPO (find me on the web, somewhere)

Source record: 37126

Try a simple OpAmp DC voltage comparator.

Reflected DC rectified voltage from VSWR meter . via 10K pot to Op-Amp +ve input.

Forward DC rectified voltage from VSWR meter . via 10K pot to Op-Amp -ve input.

Adjust the two pots for the right fail ratio.

Op-Amp OP switches HIGH when reflected power (sense voltage) exceeds the preset percentage of the forward power (sense voltage) as selected by the 10K pot ratios.

Use Op-Amp to energise relay/disable supplies/mute oscillators/energise motor to drag out the mains power plug/etc.

1726. Re: BA1404 and 38 KHz Crystal

Newsgroup: rec.radio.amateur.homebrew

The BA1404 is only really popular 'cause of the internal stereo encoder. Otherwise people would be happy with something like the http://w1.859.telia.com/~u85920178/tx/v7b_proj.htm 400mW project (bit complicated), or perhaps the http://w1.859.telia.com/~u85920178/tx/bug5.htm 10mW project (too simple). It is my opinion that the BA1404 should be left in obscurity since the RF side of it is SO unstable it is alsmost unuseable for more than a few minutes.

One would be far better to use a decent stand-alone stereo encoder, such as the http://home.intekom.com/jean/fm_stereo.htm which doesn't even use a crystal or transducer to get the 38KHz. The output of this could then be connected to a decent and stable transmitter. The encoder just uses a couple of Op-Amps and a "slack handfull" of resistors. By the way, those 40KHz transduces you get in Halfords ultrasonic car alarms have a bandwidth of +/-2.5KHz. This means that they can easily be made to scillate at 38KHz.

I hope to have a PCB available for a similar OpAmp encoder, but it uses fewer amps/stages and is based on a 4.870MHz crystal ($1 each - got a lot of them). So if the stereo encoder were available, then why would anyone in their right mind want the BA1404?

BR

Source record: 37130

Hi Harry

I'm English though despite the Swedish name! Always causes confusion not least because my XYL is Swedish and we visit a lot.

I live in the UK and the transformer manufacture is also in the UK. If I can get the 10+ price, £17.21 seems reasonable. Even compared to what I would spend trying to make up the voltages with separate transformers etc. A 250VA toroidal from Farnell costs £27.43, and that's without all the extra secondaries. Modifying an existing one by winding etc scared me, sounds like a lot of work and I don't know how to do it.

The other option was back to back transformers but I need the double HT secondaries so I can connect them in series for 250-0-250 so I can use a GZ33 full-wave rectifier tube.

I still find it hard to see how I could beat this price any other way unless I find a suitable old transformer, which I've so far failed to do.

Of course I need more orders to make up 10 <hint>

I have a magazine article that I tore out of 'Applied Mircrowave $ Wireless' magazine. Unfortunately, the even numbered pages, where the date would be, is all advertisements, so no date! Also, unfortunately, the last page of the article is lost, which would include the conclusions and bibliography.

This article describes a voltage (well, actually current) controlled inductor that can be used in an RF oscillator. The basic idea is to wind two coils on a magnetic core, like a high turns ratio transformer. One coil is the 'normal' inductor in the RF oscillator. A DC current is then applied to the other coil. The frequency of the oscillator can then be controlled with the amount of DC current.

I have tried searching the web for more information, but have not found anything. The key word in the article is 'transductor', and I have found other things called this but not what what this article describes.

Anyone know any more about this, or know a web site? The pages I have do have some interesting photographs comparing the output of two oscillators, one controlled with a varicap and one controlled with the 'transductor'. The one with the transductor has a lot less spurious output.

No flame, just some possible ways to help you (and lurkers) out in the search for stable reference oscillators... A fellow in the UK used to post offers here for some decent reference oscillators at very attractive prices; they were some power-of-2 frequency (i.e., something like 2^14*1kHz, if I recall correctly, or maybe it was 2^20*10Hz). You'd have to accomodate the freq, but the price seemed right to me. I suppose it's possible he still has a source of them. And you can get a Dallas/Maxim DS32kHz TCXO, +/- 2ppm max over 0-40C, as a sample or for $6.95 in singles. Also, you may have noticed the offer in my posting. Admittedly, you have to put up with a very limited set of available frequencies, but for me that beats trying to implement my own TCXO or oven! ;-o -- I also note that you can get very tight tempco crystals from places like International, but they are a bit pricey.

It seems like accomodating some semi-random frequency isn't much of a problem, given the ease of division by arbitrary N up through at least the HF frequencies. A key would be continued availability, if you wanted to make several copies over a span of time, or make a design easily available to others. To that end, the DS32kHz seems a good choice, provided you can use the 32.768kHz output frequency without too much trouble.

Cheers,
Tom

I recently built the 9850 DDS based on the Far Circuits board. Not a kit, but the parts are pretty easy to collect and it probably cost a tenth of Sheldon's kit:

http://www.qsl.net/wb8rcr/AD9850.html

Might be a little tougher to get things like shaft encoders and PICs in Norway but I can't believe it's all that difficult. Even with a fancy, backlit LCD I think I have less than $30 in parts, less than 1/6 of the cost of the Hands kit, (assuming the pound is about where I think it is.)

NJQRP had a page on it with some suggestions and modifications to the filter from the QST article but I can't seem to find that page right now.

NJQRP also has a little daughtercard for implementing a DDS to your specs
http://www.njqrp.org/dds/

Jim,

What you describe is a normal property of just about any inductor using some form of ferrite core. The devices were also called "Increductors" and were widely used in service-grade sweep generators. There is no inherent reason why oscillators with varicaps or saturable cores should behave differently, except perhaps at the extremes of frequency shift. If you don't need a lot of range, I'd experiment with ordinary ferrite toroid cores or cup cores.

Search also on "saturable reactor". These used to feature prominently
in power supply regulation for some military gear, and I expect that
the idea can be applied to the RF arena.

> concern with a long speaker extension!

Actually, the first thing that comes to my mind in the way of problems is "ground loop." If the 12V power that you feed to that remote speaker also powers something else near the source of the audio, you may end up with power trying to go through your audio cable, and that could be a problem. If the 12V is isolated, used only to power that remote speaker, it shouldn't be a problem. You can accomplish the same effect by transformer-isolating the audio on either end. And you should plan to run two conductors for the power, and two separate ones for the audio.

If the audio you are feeding the remote speaker is fairly high level and from a low impedance source (like an amplifier output), there's likely no need for any fancy wiring. But you might not know till you actually try it. If you don't mind having two cables, it will probably be cheapest to do it that way instead of looking for a cable with four conductors and then finding out that you needed to have the audio conductors shielded... BTW, I'd go for minimum 18 gauge for the 12V wiring.

Cheers,
Tom

Actually, Bert, there used to be just such a thing! I had forgotten
about it. Anyone know if it still exists, and how to access it? Best
I can do with a Google search is this, which talks about it being on
indefinite hold: http://www.novia.net/~pschleck/elmers/

BTW, I'd also say that sometimes a guru tries to be helpful but for
whatever reason, just isn't able to communicate with you. Someone
else may understand him very well, but for some reason, the connection
just doesn't work with you. So in that case, don't blame the guru,
just find another with whom you resonate better.

Cheers,
Tom

Duncan

Rog.

In a mod article for the Yaesu FR50B it says put in a xtal filter in the first IF chain to cure intermod. Actually I notice that if the bandwidth is 3Khz that would be setting the audio bandwidth as well as curing intermod. You could never have a bandwidth greater than 3Khz. Anyhow, if you come across something you could give me a call. Email is:

news_emailREMOVE@ntlworld.com

Remove "REMOVE".

Thanks.

Rich.

If you are looking for help with design of a short, helically-wound,
1/2-wave dipole, resonant at 3.7 MHz, then download program MIDLOAD.

Wound on short plastic tube. 50mm tube diameter is OK. You choose tube
length and overall length. Wind with thick low-loss wire. Program computes
all dimensions, wire diameter, number of turns, tube length, length of
tuning rods, etc.

Tuned to exact frequency by pruning the wires or rods extending from ends of
coil. Can be fed by ladder line or coax using link-coupling over centre of
coil.

Download in a few seconds program MIDLOAD from website below. Run
immediately.

Hi guys,

Dave has emailed me in PVT, and I liked his thoughts very
much.
Maybe one may come to this point after reading the whole
thread, but this was the earlier reply (I think).
Obviously he has given me permission to repost his email to
the NG.
On another mail, he also said he liked Yuri's idea of
coating the bamboo spreaders with latex driveway paint...

well, to Dave's reply:

Subject: Re: Spreader materials for Hex-Beam
Date: 5 Mar 2003 19:48:31 -0000
From: "Dave Platt" <dplatt@radagast.org>

<snip header>

>The question is what are the pros and cons of bamboo and
>fiberglass spreaders?
>I figure that I could get the bamboo spreaders at NO cost,
>but they will eventually rotten and break.

True 'nuff. If you do use bamboo, you would probably want
to dry it
well, and then apply a couple of coats of a good outdoor
varnish.
This would probably extent its lifetime by quite a bit by
sealing out
moisture. Probably best to varnish it _after_ bending it to
shape and
installing the wires, so that the varnish doesn't crack.

>Fiberglass material is expensive, but the way I see it may
>last many years.

Also true _if_ it's shielded from sunlight.

You might want to build one out of bamboo to see how well it
works for
you. This would reduce the cost of making mistakes during
construction and would give you more of a chance to make
adjustments.

Then, if it works well in practice, you could rebuild in
fiberglass
(either immediately, or when you first decide/need to do
some rework
on the antenna for other reasons).

>Then one issue arises... Would it be better to use
>telescoping sections of FG tubes or a solid rod would be
>better?

Telescoping sections will need some additional work at the
overlap
points. In this respect, rods would be simpler.

On the other hand, rods would probably be heavier for any
given amount
of stiffness.

>Almost forgot to mention... I live in SE Brazil (sunny,
>rainy), with a possible move to NE Brazil (really sunny,
>quite dry) in the next months

Rain will be hard on the bamboo.

Sunshine will be hard on both. I've been told that
fiberglass exposed
to direct sunlight will age fairly quickly.

Spraypainting the spreaders with an opaque sun-resistant
outdoor paint
after installing the wires would probably be a very good
idea. A
black enamel spraypaint would do the job (and would also
make the
antenna somewhat less visible).

I haven't tried it myself, so can give only a few suggestions. One would be to use a toroidal ferrite core -- toroid because the lack of a gap in the magnetic path will make saturation easier, and ferrite because it saturates much more easily than powdered iron. You'll want to use one of the 60 - series, high frequency ferrites or equivalent to get decent Q. The current will obviously have to be very clean to avoid FM, just like you need to use a very clean voltage for a varicap. And you'll have to have a good way to decouple the control current from the RF. I doubt that the temperature stability would be very good, and you're very likely to have hysteresis due to residual magnetism -- returning the current to zero won't produce the same frequency as you got before applying current. These might be tolerable in a closed loop system like a PLL, but probably not in a free-running VFO.

Good luck. Let us know what you find out.

I can second the "not powdered iron" suggestion. I tried winding a few
turns on an existing VFO and applying up to 10 ma of current. I
remember that I got almost no frequency shift. Since this was for use
in portable gear, I did not want to try several hundred mas of current
just to tune an oscillator!

1751. What VFO specs for CW working?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-08 00:48:10 UTC
From: Richard <nearlynews_email@ntlworld.com>
Message-ID: <b4beh7$1sf7bo$1@ID-150848.news.dfncis.de>
Source record: 37204

Before I start figuring on what to do VFO-wise, I'd better figure out some specs.

Lets say I want to do CW working (Never done CW BTW, just about to learn it). First of all what IF bandwidth should I be thinking of using, 250 to 300Hz?

I want to turn on Rx or Tx, then wait say 10 minites for a warm up. Then I want the rig to display frequency to within, well what, + or - 100Hz?

Okay, then I want the frequency to stay within what parameters? 100Hz per hour?

Thing is I've little understanding of what specs I should be going for in a VFO in todays environment on the bands. I certainly like to think that my Rx or Tx frequency is at least within 100Hz of true. I'm less certain of what specs I should be seeking for regards drift and retuning. Any experienced CWers have a view on these matters?

I presume specs for CW working will satisfy SSB working.

Rich.

Of course, you can always retune the VFO to get back on frequency, but if you had an IF bandwidth of say 250Hz, what is acceptable retune time, ie period between having to retune because the signal is getting too far away from where it should be in the passband.

That's awfully narrow. I prefer around 400 Hz for most operating. If you want narrower bandwidth, consider an audio filter with adjustable bandwidth. I've seen cases where new CW operators prefer a narrow bandwidth to reduce distractions. As your speed increases, though, you'll find that your brain becomes a more effective filter, and narrow filters tend to ring and blur higher speed CW, making your preference change to wider bandwidth as you get better.

> I want to turn on Rx or Tx, then wait say 10 minites for a warm up. Then I want the

The frequency display is up to you, depending on what you want to use it for. But since steps of 10 Hz or so are discernable, that might be a more useful resolution.

> Okay, then I want the frequency to stay within what parameters? 100Hz per hour?

That's a good goal. I routinely make a simple Hartley that has about 200 Hz warmup drift at 7 MHz and is adequately stable without any temperature compensation at all. It can be made even better yet by substituting some negative tempco capacitance for some of the NPO. You can find the schematic in any description of the "Optimized QRP Tranceiver" or Hayward & Hayward's "Ugly Weekender", which have appeared in various publications from time to time since their original publication in QST in the early '80s. It's also described in detail, along with a lot of good design information, beginning on p. 4.3 of _Experimental Methods in RF Design_. Incidentally, you should really get this book.

I find the little Hartley, when properly built, to be adequate for casual operating or the demands of Field Day. I once made one for 15 meter direct operation, and found the stability to be inadequate when used outdoors where the sun could heat the rig enclosure. It was, however, uncompensated. You'll find a lot of good information on

temperature compensation in _Experimental Methods. . _.

You might take a look at Hayward's _Radio Frequency Design_, now
published by the ARRL, and _Oscillator Design and Computer Simulation_
by Randall W. Rhea (Noble Publishing). If you're particularly interested
in low noise oscillators, there's a lot of good discussion in
Communications Receivers by Rohde, Whitaker, and Bucher (McGraw-Hill).

Hi,

I plan to modify an old RadioKit 75 meter SSB transceiver for 20 meters by retuning the receiver and transmitter filters. It uses a 9 MHz IF and 5-5.5 MHz VFO. Do I need to move the BFO frequency from the high side to the low side of the IF filter passband to get USB operation on 20 meters?

73,

Jim

>are a bit pricey.

A problem on "accommodation" is that the ancilliary circuitry
can get rather large. Using a 32,768 KHz stable rock means
15 flip-flops in a chain begets an exact 1.0 Second signal at
the output. That's great for wristwatches which have a little
specialty CMOS IC inside it with more flip-flops to count down
minutes, hours, days, etc. Somewhat clumsy when a PLL or
DDS or whathaveyou needing a frequency higher than 1.0 Hz
as the reference.

>It seems like accomodating some semi-random frequency isn't much of a
>problem, given the ease of division by arbitrary N up through at least
>the HF frequencies. A key would be continued availability, if you
>wanted to make several copies over a span of time, or make a design
>easily available to others. To that end, the DS32kHz seems a good
>choice, provided you can use the 32.768kHz output frequency without
>too much trouble.

The NTSC color subcarrier frequency was specifically selected
to be comparable to 1 MHz and harmonics (in addition to being
455 times half the sweep line frequency). Those are numerous,

in use by the millions in the USA. If anyone wanted to make a reference standard out of a 3.579545454545 MHz rock, they could through an intermediary PLL. Divide that color subcarrier by 315 to achieve about 11.364 KHz as the reference for a phase-frequency detector. Have a VCO at 1.0 MHz, divide that by 88 to get 11.364 KHz as the comparison input to a P-F detector, adjust the control loop filter constants to fit 11.364 KHz, no problem. Division by 315 = 5 x 7 x 9. Dixision by 88 = 8 x 11. That intermediary PLL VCO output will be locked to 1.000000000 MHz to the tolerance of the color subcarrier frequency. The integer multiplication/division ration is built into the NTSC system.

Now the extra fuss to achieve a 1.00000000 MHz frequency may be more useful since it can manipulated for a wider choise of reference frequencies. On the other hand, the reference can begin with a stable 1.0 or 10.0 MHz crystal without all the other added stuff. I'd say the latter is easier to brew up in the home shop. Mileage varies.

Add more turns (probably a lot more), or use the metal strips out of
those tags used to prevent theft in stores. Laminate yourself up a core
out of those, they have a very low saturation point, designed to
generate harmonics in modest magnetic fields.

That in itself might be an issue, if you saturate the core you'll
probably flat-top the waveform and reduce the Q of the entire system
quite a bit. Apart from the purity issue, you might stop the oscillator.

If you retune the front end to respond to the image, you will have low-side injection instead of high-side injection. Your rig will be respond to USB, without doing anything else.

I wonder if I should be talking in terms of ppm. Anyway, here are the specs of 2
modern commercial ham rigs:

Yaesu FT1000MP MK5

Frequency Steps:
0.625/11.25/2.5/5/10 Hz for SSB, CW, RTTY & Packet; 100 Hz for AM and FM

Freq. Stability:

<ï¿½ 0.5 ppm (after 1 min. @ 25 ï¿½C)

ï¿½ 0.25 ppm (after 1 min. @ 25 ï¿½C, w/TCXO-6)

Yaesu FT897

SynthesizerSteps (Mm.):

10 Hz (CW/SSB), 100 Hz (AM/FMIWFM)

Frequency Stability:

ï¿½4 ppm from 1 mm. to 60 mm after power on. @25 C: 1ppm/hour

ï¿½0.5 ppm/i hour @25 C, after warmup (with optional TCXO-9)

Neither mention frequency readout accuracy.

Okay, looking at the 1000MP. I think things settle within 1 minute to + or - 0.5
ppm. I take it that that means for a frequency of 7Mhz drift is 3.5Hz. Or 1.75Hz
with the optional TCXO. Now, if you can read to 10Hz you would not see that drift.
Your frequency looks rock solid, even though it can drift by 3.5Hz. That's
0.0000005%.

(I wonder what the ppm spec relate to. Final output or received frequency I guess.)

I notice that with the right xtals the old xtal controlled FL50B I have will drift no more than 0.001%. At 7Mhz the drift would be 70Hz. (1ppm = 7Hz, so that's stability of 10ppm). Normal xtals drift would be 0.005% or 350Hz @ 7Mhz (50ppm). Well I'm a bit shocked, 350Hz looks bad and that's for xtal control! Wonder if regular modern xtals are better than 1960's ones! I do need to change the frequency sources in my old set! That could be daunting, since there is the VFO, a heterodyne crystal, then the BFO. When I think about it, if wanted stability in my old FR50 line-up, seems like I may need something to measure the frequency of all three of these oscillators circuits. (Is it worth it if I had to do that).

Anyway, all well and good, but it's the modern practical specification that should interest me. I mean what is acceptable drift considering say an IF bandwith of 400 or 500Hz. 4ppm/hr? At 7Mhz that would translate to 28Hz/hr. That looks good. (I'd see that drift with a 10Hz readout). Would anyone here be happy with 4ppm or could one afford to have 6, 8 or even 10ppm in a CW setting? Again, we have to be talking about final output frequency I think.

Given the circuit setup in the old FL50B/FR50B that I want to mod, maybe for simplicity of modification, the stability ought to be left to be a function of an unmeasured and therefore uncompensated for heterodye xtal oscillator. I'm sure there is one in the Rx and Tx. But, if the heterodyne oscillators have 0.005% stability, that could defeat the object of making a very stable VFO. So, we are then talking about putting in a modern high stability xtal for the heterodyne oscillators, or measuring and compensating heterodyne osc drift in the VFO.

Frequency steps not relevant, inasmuch as I'm trying to simply stabilise an LC VFO.

(I'm trying to think, will the BFO osc frequency affect the received frequency. I don't think so). Rich.

Sort of going of the subject of the thread, but, heterodye osc (or carrier osc) got
to be better than 0.005%stability, because I can acheive 0.001% stability if I plug
in a good xtal. I must take a look at the subject of xtal osc stability, and figure
out stability of the xtal osc in the set.

Rhea's book is available in PDF form on the web (search for his and/or the publisher's name). It's a huge download, and many equations and diagrams have been mangled in the PDF conversion process, so you can't really learn much detail from it. Still, it's enough to help you decide whether you need to order the real thing.

Alternatively, it may be easier to order any of these books through your local public library first.

Another highly recommended book is 'The Art of Electronics' by Horowitz and Hill. This hardly deals with RF at all, but it will greatly consolidate your general background in electronics (if you don't already have that) and then you'll then be in much better shape to move on to the specialist RF area.

The beauty of H&H is that it is a rigorous college-level textbook, yet at the same time it tells you practical things that you need to know, and does it all in an easy-going way with no more math than is absolutely necessary.

It may be cheaper to retune the VFO to run on the HF (23-23.5 mhz)
side as obtaining a BFO xtal _could_ be expensive. but essentially the
answer is..

Yes you will need to change the BFO if you want to use USB on 20m with
the existing system.

Although it is true that narrow filters so "blur" the CW (the math says so), the effect really isn't significant at practical speeds (below about 40 wpm). Narrow filters do tend to have a hollow sound which can be annoying, however. Narrow filters used to have a significant ringing effect, which could make high speed, heck, even moderate speed, CW difficult, but I haven't seen that in a while, perhaps computer designed filters made that go away, I'm not sure.

A big advantage to a narrow filter is that, not only does the filter whack out interference, but it also whacks out band noise. From that perspective, the narrow filter is a big win.

Balancing that, however, is that you need to be very careful when tuning across the band with a narrow filter if you aren't going to miss most of the stations. With a little wider filter you have more time for him to press on the key before you've passed over him. I think you indicated that you have an analog VFO, I'm assuming varactor tuned, I wouldn't go more than 60 or 70 kHz wide for a ten turn pot with a filter much under 500 Hz simply from the tuning difficulty.

Someone suggested 400 which seems to me to be not a bad compromise if your filter has pretty steep skirts. If you are making up a filter with, say, 3 or 4 crystals, I'd go a little narrower since you aren't going to get real steep skirts and the wider filter won't have such a big advantage. If you are going to buy a Collins mechanical filter with a breathtaking drop off the edges, perhaps a little wider would be in order.

A common practice among QRPers is to make a crystal filter with varactors at each stage, allowing the bandwidth to be adjusted. A range of 250 to 750 Hz seems to be pretty popular for this arrangement.

>
>ï¿½ 0.25 ppm (after 1 min. @ 25 ï¿½C, w/TCXO-6)

>Neither mention frequency readout accuracy.

Since we are talking about rigs with frequency synthesis (PLL and/or
DSS), the output frequency is _exactly_ Fout = M/N * Fref, in which M
and N are integers and Fref is the (TCXO) main oscillator. The
frequency display is derived from M and N _assuming_ that Fref is
exactly at the nominal frequency (which it seldom is:-).

Thus the only source of readout error is the rounding/truncating
error, if the frequency synthesis step is different from the display
resolution. If the synthesis steps are 0.625 Hz and the display
resolution is 1 Hz, the last digit can be off by one.

>Okay, looking at the 1000MP. I think things settle within 1 minute to + or - 0.5
>ppm. I take it that that means for a frequency of 7Mhz drift is 3.5Hz. Or 1.75Hz
>with the optional TCXO. Now, if you can read to 10Hz you would not see that drift.
>Your frequency looks rock solid, even though it can drift by 3.5Hz. That's
>0.0000005%.

These rigs use frequency synthesis and the displayed frequency is
derived from the integers M and N, so regardless how much the
reference TCXO drifts, the displayed frequency does not change at all.

The situation would be different, if the frequency generation would be
based on a free running VFO and the display would be driven by an
independent frequency counter with ultra stable time base,then you
would see the drift in the displayed frequency.

>(I wonder what the ppm spec relate to. Final output or received frequency I guess.)

My guess is that the quoted frequency stability refer to the TXCO, not the Rx or Tx frequency. Measuring the TXCO frequency accurately is easy, while measuring the Rx frequency would require an external signal source and an audio frequency counter to monitor the CW beat note frequency.

It should be noted that most general coverage HF rigs use up-conversion with an IF of, say, 60 MHz, thus the local oscillator range is 60-90 MHz for the 0-30 MHz Rx/Tx range, thus with a 1 ppm reference frequency error would translate to 60 Hz when receiving LF/MF signals and 90 Hz when operating in the 28 MHz band.

My CW station is all home-brew and I have no idea what the specs are for anything about it. If something doesn't appear acceptable then I work on that problem. Operating style has a lot to do with what is desirable in CW. A station that is operating in a traffic net certainly would like selectivity wider than one trying to work DX in a pile-up. Most of my listening is while I am working on something at the work bench. If it sounds right and the reports are good then the specs are just right.

I'l say they do. I mean difficult! Take my FR50B and FL50B. The VFO can feed the RX and TX. For explanations sake, if the VFO is on 8672.4Khz, the TX output on CW is 3500Khz. Modulate and the lower sideband extends (if it is 3Khz wide) down to 3497Khz, centre of the sideband frequencies being 3498.5Khz, carrier being at 3800Khz. Okay, but the really "interesting" bit is that the RX is tuned perfectly for a CW signal on 3498.5Khz!!! A signal here is right in the middle of the RX IF passband (455Khz). Yet, oddly enough RX is tuned perfectly for a SSB signal being on 3800Khz, BFO setting being 456.5Khz.

This makes getting a correct frequency reading difficult, unless I can program in the difference between CW and SSB.

Working for 80m:

TX Rf out freq = VFO - C.O.
8672.4 - 5172.5 = 3500

RX Rf in freq = VFO - 1st IF
8672.4 - 5173.9 = 3498.5

These older rigs, don't you just love 'em. :c)

Jim:

The first response to your post is correct. You don't need to change the crystal in the BFO, you only need to change the tuned circuits. If you move the VFO to the other side of the IF, THEN you will also need to change the crystal.

This is the common way the 9 mHz IF has been used for decades and is in large part responsible for the custom of LSB on 80 and 40 and USB on 20 and above.

I'm thinking out loud again. :c)

Difficulties arise if you change from CW to SSB or use one VFO to control TX and TX.

Normally you might use these rigs a seperates. You (say) put a 8672.4 Khz xtal in the TX. You out CW on 3500 Khz. Before that you have calibrated the RX with xtal cal or with RF out from TX. Your RX VFO frequency is on 8673.9 Khz, slightly different from the TX xtal. Your dial is made to read 3500 Khz dead.

Op thinks, I'll try SSB, leaves xtal in and transmits SSB with carrier on 3.500 Khz. But, Rx needs adjusting because VFO needs to be on 8672.4 Khz for a 3500 Khz SSB signal. You tweak Rx dial so you can copy the station at the other end who has a modern rig that does not have these niggling design artifacts. But your dial only reads out by 1.5Khz, which you cannot discern anyway because the dial is not great. But you know that you are transmitting on 3500 Khz and the guy at the other nd surely is pretty close to yout trnasmit frequency.

As for calibration with the internal cal. Okay for CW, but produces a 1.5Khz error for SSB.

As for one VFO controlling RX and TX, problems. Okay for SSB. As for CW, RX wants 8673.9 Khz, not 8672.4 Khz. Yep you will hear the CW in a 3Khz filiter, but maybe not 400Hz. Modifying theYaesu 50 line for single VFO operation is not going to be a peice of cake. :c(

For even better accuracy get the color subcarrier out of a TV that's tuned to a network program. IIRC the source for these signals comes from a rubidium or cesium standard. Since all timing is derived from this frequency it allows good synchronization over the network.

Wow, I remember that set. It was in an issue of electronics illustrated
many years
ago, I probably have that issue hidden away in a box someplace. Not a
bad way to start
but a few of the parts may be hard to find. I'm sure some of the guys
on this NG may
have some dead octal tubes you could smash up for the tube bases. If
you can't find the
power transformer use two filament transformers back to back. The input
transformer
should be a 1 amp job, the output one (to provide the hv) could be a 1/2
amp unit. If you
can't find the high impedance headphones (Antique Electronic supply has
them) you can

get an output transformer out of an old AA5 and use a pair of 'walkman' phones instead.
Just connect the transformer primary in place of r7 and don't use c17. Connect the
walkman phones to the transformer secondary. Since most walkman phones have an
impedance of about 16 ohms or so and an AA5 output transformer was usually 2k to 3.2 ohms
you will end up with a plate impedance of close to 10k, just about right for the 12AT7.

Have fun!

Oh I almost forgot.....
You will need to change the coil data a little to tune the
sw broadcast bands instead of the ham bands. Add or subtract
a little from the total turns to move the frequency higher or lower.
Or change the value of C2-C7 a little (make them bigger, say 100pf
instead of
47pf and 47pf instead of 10pf) to tune a wider range.

Also look at the twinplex receiver in a Lindsay book.
http://www.lindsaybks.com/bks/twin/index.html
And look at my web site for my version of that radio.
http://www.qsl.net/wa2mze/Twinplex.html

The EI receiver is very similar to the twinplex, except ac powered.
Might be safer building a radio powered by two D cells and
10 9 volt batteries in series.

1786. How to?: connect headphone-out into microphone-in (volt,amp,Z mismatches!)

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-08 21:59:50 UTC
From: dkcombs@panix.com
Message-ID: <b4dp4m$a21$1@panix1.panix.com>
Source record: 37239
Cross-posted to: alt.home.repair,rec.radio.shortwave,rec.radio.amateur.homebrew,rec.radio.amateur.equipment,sci.electronics.design,sci.electronics.repair

(Maybe *someone* in all these newsgroups knows how
to do this -- the resulting info will hopefully
be useful to readers of each of these many, many
newsgroups.)

Am listening via net streaming-audio to an important
meeting 3000 miles away, and need to tape it, if
possible.

The pc has an earphone/headphones out, which works
fine, super quality sound coming out.

I also have a sony walkman-like casette-player/recorder,
and that has a "mic" (microphone, presumably) input
socket right next to its headphone out.

I want to use that wee machine as my tape-recorder.

(No, don't have the user-manual, which would
give me the specs for it.)

Surely there's a *huge* voltage mismatch,
tiny voltage generated by sound-waves hitting
the mike, vs what it takes to drive the headphones.

To say nothing of the impedances.

QUESTION: is there some, er, "bridge" that
I can buy that will
connect the pc's headphone-out to the
walkman-like recorder's mike-input?

If possible, I vastly prefer to not be forced
to build such a thing -- especially with
no more heathkits available!

(I just called the local radio shack, and their
"expert" said he knew of no such device.)

Thanks so much!

David

Well, I once connected the headphone output from a turntable into the microphone input of a small tape recorder through a 47K resistor - worked perfectly and cost nothing. :^)

1788. Re: looking for a HP 8568B spectrum analyzer

Newsgroup: rec.radio.amateur.homebrew

HP8568B 0-1500 MHz is really one great spectrum analyzer.... I would
easy pay 1500 for it in good working cndx. I use it as THE instrument
of choice when I need a spectrum analyzer at work....

The high freq brother is HP8566 0-22 GHz (325GHz) which is just as
good... price was something like 50-70k 20 years ago and it is still a
great instrument.

There was a variant of the low-freq, nor sure of the number might be
8567 which was intended for EMC measurement.

I doubt anyone will dump their 8566B except when it is too costly to
repair, Agilent still supports this instrument!

HP141 is several generations earlier then the 8566, but why not have a
look at HP182 or the 853 series? I know there is a similar looking
analyzer (as to the 8566) which only went up to 40 MHz, this one
should be much cheaper....

Hmmmmm
More info is needed for concrete answer. Mic input sensitivity depends
on the kind of mic (electromagnetic or electret, etc), sound card output
level is also not standard, but you can imagine your souncard output is
around 0.1 Vrms (which is a kind of standard for AUX-IN for amplifiers)
and the mic signal is mV range. so you need a voltage division by 100
... If I were you, I would take a 1K potentiometer, and woud use the
middle pin and common pin(Ground, shield) as mic input, after a few
trial and error (start by division by 100) you will hit a suitable point
by potentiometer.
Do take good care of shielding to avoid unbearable noise.
Good luck

Rat-shack sells attenuating cables.

You may, however have to get a stereo-to-mono adapter to
tap into the thing, or just a stereo splitter to get a
mono jack. Plugging the (mono) attenuating cable into the
stereo jack will short one channel. The S-2-M adapter
just ties them together, which is okayish, but the splitter
will be your best choice. Since your meeting is presumably being
streamed in mono, pulling either channel in would be fine.

Tell the drooling droid at RS:

Part number for Stereo-to-Mono adapter: 274-374
Part number for Stereo-to-Mono splitter (preferred): 274-375
Part number for attenuating cable: 42-2152

You may be able to buy an attenuating cable. You might even try hooking up the audio-out from the PC directly to the mic input of the tape recorder using a regular (non-attenuating) cable. I've done that in the past and it worked OK - of course that's no guarantee that it would work for _you_.

You could also try using a few resistors to build a simple voltage divider that would lower the output voltage from the PC.

OTOH (or is that "OTOOOH" by this time?? ;-), this thread started looking at VFO stabilization to a crystal reference, presumably with steps of 10Hz or less, and the simplest way I know of doing that (a FLL) requires only a reference around 10Hz or a bit less, and perhaps four bits of counter, latch and subtracter. A 32768Hz source actually makes it pretty easy to get an 8Hz reference: 12-bit binary divider. That's 20 f/f's, some logic, and a tiny state machine. Should be able to fit everything into a small (32-36 f/f) CPLD. Probably need a mid-size (64-72 f/f) CPLD for a somewhat better PLL implementation. A really _good_ pll implementation, with superior phase noise, is going to be more complicated no matter how you cut it. But I think we were starting from a "KISS" viewpoint here.

Maxim/Dallas also sell higher freqeuncy TCXOs, including 10MHz. They're a bit more expensive, but not bad. But I've gotten what should be a lifetime supply of TCXOs and OCXOs just from scrounging; most are useful freqs like 5, 10, 20 and 100MHz. Boards with very decent oscillators are tossed into the trash. I'll bet if you could find a broken GPS, you could find a good oscillator, likely in working condition. I have some GPS boards with nice little 10MHz oscillators on them (but still working as GPSs!). But again, it's that tradeoff of cheap parts versus the ability to have others replicate a circuit easily. Perhaps a board layout with an easy way to patch in a variety of small oscillators, or an external oscillator signal, is a reasonable way to go.

Cheers,
Tom

anyone got any info on where to find details on homebrew analyzer??
preferably using catv or similar tuner..
Have analyzer at work but would like something simple at home..only using it
to set up amps..filters etc..doesnt need to be very accurate...

thanks simon g0zen..

still looking for 10ghz frequency counter info..

IIRC Radio Electronics magazine published a project just
about like you describe. I don't remember the issue, maybe someone
on this NG has a copy and can scan it.

What you need is an impedance matching circuit. Simplest thing
is to go to Radio Shack, Fry's or some other electronics store
(Best Buy might even have it) and look for either an attenuator
or dubbing cable.

If you really wanted to do it yourself (though you probably won't
save anything over buying a low-end ready made cable or plug)
a non-polarized electrolytic capacitor and a potentiometer would
do. (You could use a resistor, but since you don't have the specs,
might as well make it adjustable - a tiny pc-mount pot would do.)
You can buy a cheap cable with the appropriate plug and socket,
then cut it in half and wire your circuit into the middle. Do a web
search and I bet you find sample circuits.

Here's the circuit I've used. Value of the parts isn't super critical. A
,47 uf cap and a 1K pot are probably fine. Connect the shield (outer
conductor of the cable) from the input to the output and to one
side of the pot (the middle connection on the pot is the wiper, you
want one of the side connections). Connect the other side of the
pot to the input cable's center conductor. Connect the capacitor
to the wiper, and connect the other end of the capacitor to the
center conductor of the output cable. Done. Center the potentiometer
and hook it up. Adjust the potentiometer until you get a decent
recording level. It's crude, but it works (usually). You might have to
go to a 10K pot (doubt it), or down to a 500 ohm pot, but IIRC,
1K works for most headphone outputs. Mostly what you have is a
voltage divider that drops the voltage to something the mic input
can handle.-Wm

There have been plenty of those described, I think the original one
using a cable tuner was in Ham Radio, maybe September 1986. There
was a followup or two in that magazine, and Communications Quarterly
had a few, including, I think, by Peter Bertini who posts here.
They were all variations on the theme of a cable tuner or converter,
an IF strip, and something to sweep the tuner.

Radio Electronics had a number of similar projects in the later
years. Some really simple, some really complicated.

Specific dates (which I don't happen to have handy) won't
be much use if you don't have access to the magazines, but if
you can find the magazines in someone else's library, or at a public
library, it shouldn't be much work to look through the annual
index.

All of them had relatively wide IF bandwidth, and most were
not even close to being precision.

Up until about 25 years ago, the sort of thing we'd see in
the ham magazines was more a bandscanner, ie wide enough to
look at one ham band at a time. The basic principle is the same,
though just not wide coverage.

The best article I ever saw about spectrum analyzers was Wayne
Riders article in Ham Radio back in 1977, either the October or
November issue. It covered something like 0 to 100MHz, but for
the time it was the most advanced we'd seen in the hobby magazines.
I'm not sure one should build it today, but since the circuitry
was discrete, it gives a better idea of what's involved. He
also goes into some of the design considerations, which is still
useful now.

Wes Hayward sort of went over that territory in QST a couple of years
back. Unlike most projects, he dropped the tv tuner (and the wide

range) opting for more traditional components, and about a 0 to 100MHz sweep range. It was the August and September 1998 issues. Well worth reading, for background if nothing else. He has a page up about it at http://users.easystreet.com/w7zoi/SA.html and he mentions that the articles are available in PDF format at the ARRL site.

As someone said, this is an old technique, though you don't see
it that much.

My 1978 edition of "Amateur Radio Techniques" mentions the scheme
on page 148. He mentions a February 1965 issue of Wireless World,
and mentions sightings of the scheme as far back as 1949.

I have no idea where I might have the article, but there was something
in QST sometime between 1977 and 81.

I think you should look in the books you have, or buy some books
aimed at beginners, and just build something. If you're just
trying to learn, anything will be fine. We still haven't solved
your problem with the DC receiver in that new book, and since it
sounds like a relatively simple receiver (unless you lucked onto
one of the complicate DC receivers), if you can't get it to work,
trying something else may not solve the problem.

Someone pointed to a receiver from almost forty years ago, but
realistically, there is nothing particularly great about it. Likely
it is simply available on the web. There must be tens or hundreds
of similarly simple receivers written about over the years, and
they all would tend to be of the same level of performance.

Someone suggested a one or two transistor receiver. That has
it's merits, since it won't cost you much in parts or effort.
I took it as a hint at a regenerative receiver, which has
the advantage of also showing you something about an oscillator,
since Armstrong basically discovered both at the same time.
In recent years, Charles Kitchin has written quite a bit about
regen receivers (and about superregen receivers too, but they
wouldn't be the best choice for shortwave).

Kitchin, Charles. "A Simple Regen Radio For Beginners", QST
magazine, Sept 2000, pp 61-64.

Kitchin, Charles. "High Performance Regenerative Receiver Design",
QEX magazine, Nov/Dec 1998, pp 24-36.

Kitchin, Charles. "An Ultra Simple W1AW Receiver", QST magazine.
May 1997, pp 34-35.

Kitchin, Charles. "Regenerative Receivers: Past And Present",
Communications Quarterly. Fall 1995, pp 7-26.

A similar article to that last one appeared in Electronics Now
for March 1994, "THe Lost Art of Regeneration".

One of his regen designs appeared in one or more ARRL Handbooks
a few years back (again, don't confuse it with one of his superregen
designs, that has appeared a couple of times in the Handbook).

He's had a few other articles on regen receivers in QST, most
recently the September 2000 issue, on page 61.

You might look around the ARRL site, http://www.arrl.org to
see if they've put one of his regen articles up there.

If you don't have any of the paper references (or know noone
who does), do a websearch with <"charles kitchin" regen>
as the searchwords, and you'll find material, either his own
or variations on his work.

Just about any ARRL book is going to have some sort of simple
receiver. What it will be depends on the era; 35 years ago
it would have been a regen, thirty years ago a direct conversion
receiver, then more recently a superhet.

Once you have a regen working, you could add a converter ahead
of it, and get a basic superheterodyne receiver.

Hello everyone,

Here in the U.S., I just take my image file down to Kinko's Copy, and they run off a transparency image for me on their black and white laser printer. It's always worked well. It costs me something like a buck a sheet.

I used to work with positive-acting liquid photoresist. GC Electronics makes it, and you can often find it in a spray can at Atex Electronics in San Antonio, TX. Atex is also online. But I've found dry-film photo-resist to be much easier and consistent to use. I get negative-acting film from Think and Tinker, in Colorado; they sell it in rolls of 50, 100, or 500 ft., from what I remember, and the cost runs about a buck a foot (very reasonable). They say that you have to use their expensive laminating equipment (otherwise your house will burn down, your kids will grow up to be wierd, and your dog will run away), but that's not the case at all. Using a 5% alcohol solution (to pre-soften the adhesive on the film), I apply the film to the board by hand, working the excess moisture and wrinkles out of the film with my fingers. After this has been achieved, hard pressure applied with a soft rubber roller (from a junked typewriter) works out any excess moisture which may still be present (important in order to prevent bubbles under the film). The board should be baked for 10 minutes in an oven at 200 deg F to firmly adhere the film to the board, and then exposed with your artwork after it cools. I use a 500W quart halogen worklamp from Home Depot. The lamp costs $9.91 here, and exposes the board in 25 seconds at a 12" bulb distance. Sodium Carbonate (available at pool supply or hardware stores) is used as the developer, and is quite cheap and safe to use. Now that I do it this way, I don't know why I ever used spray resist, but to each his own. I can supply more details if anyone wants to know.

> complexity.
>
One thing that happens is that when something becomes commonplace,
the explanations tend to go away. A forty to fifty year old ARRL
single sideband book covers the basics of that mode better than many
of the handbooks in more recent decades. Back then, they were explaining
it to everyone, and later material is derived from that. (Really recent
ARRL Handbooks seem to do a more comprehensive job of dealing with
SSB, but I still say the early articles are the best.)

Some of the better material of the type you seem to be looking for
have appeared in magazines, rather than hobby level books. Back in
1974, or 75, QST ran a series "Learning to Work with Semiconductors"
that went into explaning what the different components were for,
including basic calculations. For a while, it was reprinted as
a booklet, but it never made it into a real ARRL book (though
tiny snippets seem to be in "Solid State Design...". It was
a time when calculators were just becoming available cheap,
and that gave permission to show the calculations for determining
component values.

I can think of some other articles that covered more specific
things, and tended to give a better part by part description
than many books and construction articles.

I don't know if they are still in print, and while I would
describe them as being aimed at a lower technical level,
they don't give that blow by blow description that you want.
"W1FB's Design Notebook" (1990) and "W1FB's QRP Notebook" (1991)
both by Doug DeMaw and published by the ARRL. The good part
was they were both relatively cheap; each were under twenty dollars
here in Canada. But I suspect there is a lot of overlap, in
area if not material, with that new ARRL book you bought.

Often, the choice is a hobby book that is mostly construction
articles, or text books that are more theory based. There is
very little middle ground, that covers practical component selection.
I think I've picked it up through osmosis, looking at construction
articles over the years. If it's this frequency range, use
this value of bypass capacitor, if it's that range, use that value.

That's the magic behind a 9-MHz filter with a 5-MHz vfo.
You might consider adding a simple bandswitch to change
the front-end preselection to permit dual band operation.
Should be very doable!!

Weren' the huff'n'puffs simple one digit counters that
provided a DC correction to a varicap in the osciallator?
IIRC, they worked best on oscillators that good short term
stability to begin with. Ham Radio ran a bunch of construction
articles on the technique, and HR is now on CD.

This is probably the reason that LSB is the standard on 80 and 40 while
USB is standard
on 20 and above. Many early SSB rigs used the band image technique to
cover 80 and 40
and most just used a single bfo crystal. I guess a band image rig could
also be built using a
5 mhz crystal filter with a 9mhz vfo. I'm suprised this didn't happen,
5mhz war surplus
ft243 crystals were probably more common than the 9mhz ones, but a 9mhz
vfo wouldn't
have been as stable.

Thanks for the wealth of suggestions! This is a great newsgroup.

I'm still working on my first circuit, which I now realize was probably more complicated than a true "beginner" circuit. But I did learn that winding coils on pill bottles for Hartley oscillators doesn't work all that well (it'll oscillate, but if you get your hand within 2 feet of the coil, or blow on it, it will jump like a jackrabbit). I procured some ferrite rods from an elmer friend. I need some torroid cores still. Problem I have is I end up with way more inductance than I want with only 1 or 2 turns!

It's a lot of fun. I enjoy the learning aspects more than getting a functioning radio (I've already got many of these), although it would be nice to eventually end up with one!

73,
Bert

I'll bet you breadboarded that circuit. If you had built it on a metal
chassis with a metal
front panel your problems would go away. You could also use a bread
board with a sheet
of metal tacked to the bottom of the board and to the backside of a
wooden panel (connected
together and grounded) and the 'hand effect' would also disappear.

There are a number of good ways to breadboard RF circuits. My favorite is "ugly construction". Start with a piece of copper-clad PC board material. The copper makes the ground plane. Solder grounded components, stood up on end, directly to it, and suspend others over it by soldering between grounded components. You can use high value resistors as standoffs where you need to span several components between grounded ones. ICs are laid down "dead bug" style. See if you can find a copy of "The Ugly Weekender" by Hayward & Hayward, originally published in QST in August 1981, but reprinted in a number of ARRL publications over the years. It shows the method in detail -- plus it describes a simple and good-performing 40 meter transceiver.

People are sometimes disappointed when they transfer an "ugly" breadboard to a PC board. It's much harder to maintain a good quality ground on a PC board than it is on an "ugly" breadboard, so the breadboard often works better than the PC board version. There's no need at all to make a PC board unless you intend to make several copies, are working at very high frequencies where the trace and pad impedances are important, or are working with surface mount components. You can do some "ugly" constructing with surface mount components, but I've found them to be pretty fragile. Leaded components tolerate board flexing much better than surface mount components. The metalized ends tend to break off the surface mount components when things flex, unless they're mixed in with some leaded components to take the stress.

Why does the LM324 op amp need only one voltage supply when the LM741 needs two? Can anyone help enlighten me on the difference between the single-supply and dual-supply op amps?

I recently realized that the LM741 needs both supplies, even for amplifying positive DC voltages. With only the positive supply present, an input of 0V produces an output supply of AT LEAST .3V (even more with enough gain) regardless of configuration.

According to the literature and some circuit designs I have seen, the LM324 only needs one power supply. But in PSPICE, the LM324 needs two power supplies. Does the LM324 have an internal DC-DC converter or some other method to provide the negative power supply? If the LM324 only needs one power supply in real life, then why does it still need the second in PSPICE? Have I stumbled upon a limitation of PSPICE?

The LM324 is designed for +5v TTL compatibility. The LM741 is not.
The specs on the LM741 are better than the LM324 unless you require
a single voltage supply.

It largely boils down to common mode range. If you run a 741 between +5 and -5 volts, the input common mode range might be +/- 3 V (guessing here). Now if you run the thing between ground and +10V, you have to be sure the input voltage on NEITHER input pin falls below +2V. You can operate a 741 off a single supply if you are AC coupled, and the inputs are biased up at half the supply voltage. You don't need DC/DC converters to have the common mode range extend to ground. They might use PNP emitter follower or JFET inputs. Look at an LM324 data sheet, it should explain everything.

The difference between single and dual supply op amps has to do with internal design. Single supply op amps don't have any internal negative supply -- the internal circuitry is designed to operate normally when run from a single supply. But then of course you can't swing its output beyond its supply terminal voltages. Some op amps can tolerate inputs a bit beyond the supply terminal voltages, though, because JFETs, for example, can be biased this way and still operate normally.

Of course, you can float a single supply op amp between positive and negative supplies or a dual supply op amp between ground and a single supply. But you have to make sure you keep the input and output within the specified ranges relative to the supply pins, and this is often inconvenient.

I don't know anything about the SPICE model you have, but I'd look for another one if the one you have doesn't seem to mimic the real device.

You can run any standard op amp on a single-voltage supply. The op amp itself can't tell the difference between a single supply and a dual/split supply! The op amp has no "ground" pin and it really has no idea what the system-ground voltage is.

The real factor which distinguishes between "single-supply" and "dual-supply" op amps, is more properly the question of the input and output voltage ranges. Many op amps will not behave properly if their IN+ or IN- pins are pulled to within a volt or three of either voltage-supply pin - they may fail to deliver their specified behavior, or may exhibit some fairly gross problems such as latch-up.

Similarly, many op amps cannot drive their output all the way "to the rail" - there may be a range of 2-3 volts between the op amp's most positive output voltage, and the positive voltage supply.

In both cases, you can probably figure out why this is the case by looking at the schematic (detailed or simplified) in the manufacturer's data sheet. Figure out what will happen if you pull an input pin all the way to one of the supply rails. You'll often see that you'll force part of the input circuitry into a weird state... forward-biasing the junction on a JFET or something like that. Look at the output circuitry, and see why it's not actually capable of pulling the output all the way up to the rail.

Older op amps like the 741 tend to have fairly large "no go" voltage ranges... circuits using them shouldn't try to drive inputs to within a couple of volts of the supply rails, and should't expect output voltages outside of this range.

You _can_ use an op amp like this with a single voltage supply, as long as your input and output voltages will be within acceptable ranges. For example, driving a 741 from +15 volts, and using it to buffer the output of a trimmer-potentiometer arrangement where the pot's output would always fall between +5 and +10 volts, would probably work just fine.

Newer op amps can be designed with 'rail-to-rail' inputs and outputs... the inputs can safely be driven all the way up to the

positive supply voltage, all the way down to the negative supply voltage, and the outputs can often go the whole way as well (although perhaps not with a lot of current-drive capability). The rail-to-rail inputs are often safe (predicable) even if you drive the inputs past the rails by a few tenths of a volt.

An op amp of this sort can be used with a single voltage supply with one side grounded (e.g. +5 and ground) and be able to handle signals in this entire voltage range, or at least all the way down to ground.

This is what you'll usually see, in the spec sheets for a "single supply" op amp.

>According to the literature and some circuit designs I have seen, the
>LM324 only needs one power supply. But in PSPICE, the LM324 needs two
>power supplies. Does the LM324 have an internal DC-DC converter or
>some other method to provide the negative power supply?

Nope. It just has internal circuitry which won't misbehave if the inputs are driven all the way down to the negative rail (which would be at 0 volts in most single-supply situations) and which can pull the output all the way down to ground.

> If the LM324
>only needs one power supply in real life, then why does it still need
>the second in PSPICE? Have I stumbled upon a limitation of PSPICE?

I believe that the "single supply in real life" reflects the actual usability of the LM324. The PSPICE model reflects the internal circuitry, which _does_ have two supply inputs which source or sink current into the internals.

To model the use of an LM324 in a single-supply application, just connect the negative supply input to 0 volts DC.

Hi Jason,

You should dust off your undergrad lab books. Look at your 2nd or 3rd year work that you breezed past. The issues above are very elemental.

Get away from PSPICE or any derivative of SPICE and get back into the lab. You should really try learning one thing at a time, and that one thing should be the Op-Amp NOT a software package.

Thaks, Roy, for trhe response. And all the others too.

Right now I am just curious as to how well they work. I hadn't thought of the temperature stability problem, but it makes sense. Of couse you would have this same problem with any oscillator circuit.

I was curious because the article I have indicates that the IM products are a whole lot lower comapred to a varicap. This is when used in a bandpass circuit.

Probably, the best answer in the thread.
Whether a device is mentioned as dual or single voltage device is
based on some understanding when it was written. A lot of designers
once believed that op-amps needed + and -15V to work properly.

uA741 won't operate properly below 10...12V supply, but in my Apple
2e+ computer it was run on +5V (cassette interface). It was rather
uncertain if it produced error or not, so you needed to play the
cassette several times, but an RCA 3140E improved very much on this.

Motorola and National made the Norton type op-amps which were supposed
to be for single supply, but I don't really believe they became much
popular. LM358 and LM324 will run properly on low voltage, but the
output swing is rather limited. The output may be pulled down to
ground (negative rail).

>Similarly, many op amps cannot drive their output all the way "to the

>
Here, in fact uA741 is better for dc voltage below, but close to +Vcc,
and a good reason for keeping some in the junkbox. It may amplify
signals close as 0.6V to +Vcc

Yes, it is always important to understand why and what happens inside,
it is bad that several modern devices aren't properly described, and I
am not particularly talking about OP-amps. It is many interesting
applications you can use a device for, but data isn't proper.

Source record: 37181

The temperature stability is likely to be worse with the saturation-tuned circuit than with a conventional one because of the material you're stuck with making the inductor out of. If you're making a conventional one, you can use materials that are relatively temperature stable, like type 6 powdered iron. For the saturation tuned oscillator, you're pretty much stuck with ferrite unless you're willing to use a *lot* of current. There's also the possibility that the amount of saturation will be a function of temperature, which will further degrade stability.

I's suspicious about intermod in an oscillator -- there should be only one frequency present, so there's nothing to mix with. Harmonics will mix only to make other harmonics. If the tuning range is limited, harmonics can be taken care of with a filter.

I haven't made a varicap oscillator myself, but know that there are techniques to keep the output pure and low noise. I'd be sure that a poorly designed varicap design would be pretty ugly, but I also know they can be made to be quite clean. I'd take a look at Rohde, Whitaker and Bucher's _Communications Receivers_ for some ideas.

One of you had it right to start with and then changed his mind.

You DO need to switch side bands when going to 20 meters.
If the SSB signal is generated at 9 MHZ and a 5 MHZ vfo is used, the
side bands do NOT get inverted when going from 80 to 20.

Figure it out. 9000 - 5000 = 4000. Modulate the 9000 khz with a 1 khz
tone in the lower side band position. The tone will be at 8999 khz.
8999 - 5000 = 3999 khz. The tone is 1 khz below the carrier as would
be expected.

Now use the same 1 khz tone still in the lower side band position
(8999 lower side band signal) and add 5000 rather than subtract it.
8999 + 5000 = 13999 khz. You still get the lower side band on 20
meters as you did on 80 meters. The carrier frequency is at 4000 on 80
and the carrier frequency is at 14000 on 20 meters. the tone is 1 khz
below the carrier in both cases. The side band does not invert.

If the side band signal was generated at 5 mhz and a 9 mhz vfo was
used then it would invert. Any time you move the side band signal from
below the vfo signal to above it, then it inverts.

In generating the side band signal at 9 mhz, to get on 40 meters you
need to triple the vfo to 15 mhz (actually 16 mhz). This puts the vfo
above the side band signal and also inverts it.

One other note on putting the rig on 20 meters. You will probably have
to install a 15 mhz trap in the driver stage to the final to get rid
of the 3rd harmonic of the vfo. It will be too close to 14 mhz and
will appear in the output.

I think the DSP filters I can make on my computer ring a good bit less
than the steep IF filters in a radio. Actually, they hardly seem to
ring at all .
>
> A big advantage to a narrow filter is that, not only does the filter whack
> out interference, but it also whacks out band noise. From that perspective,

True, but if by whacking out the band noise, some of the desired
signal is lost, sometimes the s/n ratio will not improve much. I like
that aspect of it, but I don't like to get carried away with it. Cut
too much, and you start cutting part of the frequencies of the signal
you want to hear. It will vary with cdx. I've had cases on say 160m,
where a wide open SSB filter was better than a narrow one, but I've
also seen the reverse.
>
>
>

> are going to buy a Collins mechanical filter with a breathtaking drop off
> the edges, perhaps a little wider would be in order.

Probably a good idea. Myself, I vary according to the band cdx. If the
band is not crowded, I usually run about 1000 hz. My best CW rig is a
TS-830. It's VBT will tune from 500-2400 hz continuously with just the

stock SSB filter. With the 500 hz CW filter, it's about 150-500 hz using the VBT. At 150 hz, it's so tight as to be almost unusable. In the real world, I almost never use the 500 hz filter. I usually use the SSB filter and the VBT to tune about 1000 hz wide. I'll crank down to about 500-600-700 hz if the freq gets busy. The "500 hz" with the SSB filter is not as steep as the actual 500 hz CW filter. I actually prefer it wider most of the time. I don't like the pitch of the "band noise" with the tight CW filter. It's kind of annoying to me. But I can change the pitch with the IF shift.
With that radio I often use the notch to cut "band noise" on 160m. It works well, and it's variable pitch. I peak the signals with the IF shift once the VBT is set to the width I want. Only in a busy field day or contest type deal might I use the narrow CW filter. But even thinking back last summer, I think I used about 800-1000 hz most of the time on 80/40 meters. I can narrow it up with a quick turn of the VBT knob if I need to. The 830 spoils me on CW compared to my other radios. :/ It really works well. And it's a 20 year old radio too. Add my outboard computer DSP to it, and it's really killer. But that's overkill for the 830. It doesn't really need it. I use it on the IC-706 more. I don't have a CW filter in my 706 yet. The DSP filters work pretty well for it. I do need to get a real filter though for portable use though. I'll probably get a 500 hz, although the 350 hz is a bit cheaper I think. Anyway, 400 hz is a pretty narrow filter in most cases if it's steep sloped. About as narrow as I would ever use, even in a worst case.
Some like the razor blade narrow 200-250 hz filters, but not me. MK

Hi,

I have bought a second hand Zetagi M27 (http://www.zgitaly.it/)
antenna tuner this weekend with intention to modify it for ham band
use.

My intention is to substitute the internal coil with two terminals so
that I can have several coils and plug in whichever is more
appropriate for the band in use.

My questions are the following:

- Would it be worth removing the variable capacitors and mounting
them isolated from ground so that the circuit could be modified into a
T network instead of a PI network?

- Would it be dangerous as to RF exposure to mount the terminals so
that the new coil is _outside_ of the box and can be changed easily?
The TX power will be 100W.

Thanks,

ec3dds - Toni

Tony, take a look at this page...
http://www.qsl.net/m3msm/atu/atu.htm

I've used the capacitors from the M27 in its construction and it works
fine on powers up to about 50 watts. I don't think I'd like to try it
at higher powers though.
BEWARE the capacitor mounting screws, they are a strange thread and
very easily damaged. I had to re-tap with 4BA when I stripped mine ;-(

Yes. Running one of the old transmitters is a lot like running a steam locomotive. You have to pay close attention or ... boom! But, at least you can see all the parts without a magnifying glass. One knob tuning? Who want's that? I LIKE to adjust things. My old GO-9 transmitter had about 14 adjustments between the VFO and the antenna. It gave you something to DO.

1840. What crysal filter should I use?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-10 17:20:06 UTC
From: Richard <nearlynews_email@ntlworld.com>
Message-ID: <b4ihcq$1t456n$1@ID-150848.news.dfncis.de>
Source record: 37193

Hi.

In order to prevent overloading the 2nd mixer that follows, I need to substitute a simple LC resonant circuit for a crystal filter in the 1st IF section. The carrier frequency of a signal will land on 5172.4 Khz. Because the way the rx works, a 3 Khz wide LSB signal on 80/40 or a 3 khz wide USB signal on 20/1510 would extend from 5172.4 Khz to 5175.4 Khz.

The way I've arranged things, any filter must pass the CW signal without attenuation on 5172.4 Khz and must also pass SSB whose carrier is at 5172.4 Khz. (If I ignored the CW aspect, I know, I could put in a 3 Khz wide filter centered on 5173.9 Khz, but I cannot ignore the CW signal).

My thoughts were that since my main filtering will be at 455Khz, I could put in a 6Khz wide filter centered on 5172.5 Khz. This way I could receive USB on 80/40 and LSB on 20/15/10 if I wanted to, and a CW signal is bang in the center.

If I'm not going to want to listen to USB on 80/40 or LSB on 20/15/10 I guess something like a 4Khz filter would do, with the CW signal having to be slightly off the centre.

But, given my main filtering would be on 455 Khz, could I just as well use a 10, 20 or 30Khz filter?

(In practice, center frequency may be moded, I mean, where do you get filters centered on 5172.4 Khz). :c)

Thanks for your help. Rich.

My mods mean I cannot ignore the CW signal on 5172.4 Khz, a filter has to pass it.
Interestingly the companion TX (FL50B) incorporates 5173.5 Khz xtal filter, so there
might be some around.

Gary:

You are correct. I was one of the those who had it wrong before. I had done the math in my head and I'm not so good at that. I had also been thinking of Anthony Vitale's "Cheap and Easy SSB" from many decades back. He used a 9 mHz IF and 5 mHz VFO to get both 80 and 20 meter SSB. My memory (faulty) told me the LSB/USB selection was automatic, determined by the mixing scheme. I went back to look at his article and discovered that he used a sideband selector switch to change from USB to LSB; it was not automatic.

And my old Swan 350, which only had one BFO crystal and automatically provided LSB on 80 and 40 and USB on 20, 15 and 10 meters had, as you described a 5.?? mHz IF and higher frequency VFO.

Thanks for clarifying this.

>

As I stated, Roy. The incomplete article I have compared two bandpass filters, not oscillators (of course the end of the article is missing). One used a varicap and the other used a saturated inductor for tuning. They did a standard two tone test. There was a significant reduction in the 2nd order intermod with the saturated inductor. A definite but less significant drop in the 3rd order intermod.

Maybe if they aren't good enough for oscillators they might be ok for preselectors or transmitter filters.

1845. AD9854 question, no output...

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-10 20:42:36 UTC
From: Jan Wagner <jwagner@cc.hut.fi>
Message-ID: <b4it63ibp1@nyytiset.pp.htv.fi>
Source record: 37048

Hi,

surprisingly, I've managed to get the AD9854 to behave without much trouble, wow. I'm running it in parallel mode, update clock switched to externally controlled, and PLL turned off for now.

Ok, maybe less suprising, there's a "little" problem - there isn't any AC output on the I1 I1B I2 I2B pins, just some very boring DC levels. The AD9854 should have some data loaded into the frequency 1 register, but this just seems to kick the DC levels around, and still no sine output.

Maybe some of the AD9854 experts here could help me and suggest where to check for possible errors? I've checked almost everything and everything _seems_ ok but it still refuses to work... :-(

Here's some measurement data:

RESET 10kOhm to +3.3V (drawn low by the microcontroller)
PLL pin 3.3V
R-SET pin 3.9kOhm (as in datasheet) to ground, 1.24V
C-bypass 220nF to ground, 2.27V
I2 0Vdc
I2B 200mVdc
I1 500mVdc
I1B 100mVdc
I1, I2 resistors 56 ohm to ground
I1B, I2B resistors 25 ohm to ground

the AD9854 draws about 120mA even while RESET is held high. Is that ok??

all +3.3V rail decoupling caps are 220nF ceramic SMD
all resistors are 0805 chip resistors
all AVdd and DVdd pins are connected and decoupled with 220nF
all ground pins are connected, and some N/C pins are grounded
(shouldn't matter, right?)

You can see my AD9854 init source code at
http://www.hut.fi/~jwagner/dc-rx/firmware/MSP430-fw-dds.c

Basically, after RESET is pulled low, the io update clock starts putting out pulses. So the micocontroller does

DDS_writeByte(0x00, 0x1F); // 0x00=data, 0x1F=address

And the io update clock turns off, as expected. The 0x00 should also set mode 000 "single tone". Then the microcontroller is set to take over the

clock (uC ad9854-ioclk pin set as _output_ pin). The rest is a bit lengthy, you can see the register writes in the source code.

The freq 1 tuning word is still all zero after initialization stage, so a DDS_setFreq_kHz(50) tries to set 50kHz by writing something into that 48 bit register. The update clock is pulsed after each 8 bit transfer as it probably is supposed to be done, i.e 48/8=6 times for one full frequency register transfer. (hmm, uh-oh, i got a creeping suspicion here...)

Something must be slightly flawed here, but I can't find it... Any ideas?

Help and comments would be highly welcome!

many thanks!
- Jan

Hehehe, you have got to be careful. What I said above
is not true. Why? Because flipping over sidebands (on
80 from LSB to USB, on 20 USB to LSB) whilst
accommodated by a 6Khz filter centred on 5172.5 Khz in
the 1st IF, will not be accomodated by the 3 Khz wide
455 Khz filter in the 2nd IF. Swapping sidebands
whilst on a particlar band, will put the sideband into
the stopband area of the second IF filter. Unless one
made provision for a xtal change, one of 3 Khz that
flipped the carrier frequency in the 2nd IF to the
opposite skirt of the filter.

Hi Roger,

Yes, I have to stop and think about it sometimes too. If I forget to
do the addition I get it screwed up. I have a 20A, same mixing scheme
as the "cheap and easy". I couldn't remember if I had to switch side
bands or not when going from 80 to 20. Did the addition and
subtraction to prove it.

What is backwards is the vfo tuning from 80 to 20.

In the early 60s I had built part of the W2EWL "cheap and easy side
band" rig. I used part of the circuit of it and parts from other rigs.
Wonder if you built one?

Here's another 40-year-old radio that should do a good job, and in
particular should be able to drive a speaker easily:

http://www.jvgavila.com/compac.htm

Note that you wouldn't have to use that particular tube; a dual triode
(12AU7, 12AT7) followed by an output tube (6AQ5, 6AK6) would be one
non-compactron approach.

Just something quick to note, don't know if it's the problem.
The AD9854 has a mulitplier in front of
the DAC for which its default multiplier value is zero.
Therefore, you'll get DC at the output of the DDS until the multiplier
is bypassed or its multiplier value is raised.

Hope this might be the problem.

I haven't tried anything else. The temperature drift is that of the inductor itself -- heating and cooling the active device makes just about no difference at all. It starts readily, and operates over a wide voltage range. The frequency changes very little with supply voltage. The output is adequately clean and reasonable in amplitude. It's just about as simple as an oscillator can get. And I've never built one that failed to work, even up to 100 MHz. So I have little incentive to try anything else.

The one shortcoming of the FET Hartley is that the output amplitude is determined by the pinchoff voltage of the individual FET. So if multiple copies are being made, some accommodation should be made to compensate for different output levels. In that one respect, a bipolar transistor Hartley or Colpitts would be better. Whatever you design, a can of spray cold will tell you pretty quickly if you've done something seriously wrong with regard to temperature sensitivity.

There was also a receiver in popular electronics for 1967 that used a 12at7 and a 6ak6. It was
a band switched sw regen with one triode of the 12at7 used as a reflex grounded grid rf stage
and a grounded cathode af stage, the other triode was a regen detector, and the 6ak6 was
the power output stage. Used mini-inductor coils except for a 71-osc as the bcb coil.
I have this issue of PE someplace, if I can locate it I will scan it and post it here.

Gary:

No, I could never put my hands on the audio phase shift network, except by paying retail. It is still one of those things that may or may not happen. I did find somewhere an RF phase shifter (90 degrees shift from .5 - 1.5 mHz) made by Westinghouse, but it is still on the shelf.

They also sell professional carbide drill bits which work very well.
I don't know of any shelf-life for the film; I've had mine for about
6-8 months, and it still works fine. But you can call them and ask.
It's preferable to store it at room temperature or lower, out of the
sun, etc. Keep it wrapped up in the black plastic and in the box
that it comes with unless you're cutting off a piece. Direct
incandescent lighting probably will not spoil the film while you are
working with it (at least not for several hours), but when I open the
roll, I open it in a darkened room anyway, with some incandescent
lighting coming from another room. Don't open it in flourescent or
daylight; with repeated use, the UV content may spoil the roll.
Extended periods of high heat will also spoil it. Putting it in
perspective, though, normal levels of flourescent lighting aren't
going to start spoiling a laminated board unless it sits out for for
than 5 or 10 minutes. In their info about the film, they also say
something about processing the board within 8 hours of laminating it.
Basically that's a cover-your-behind parameter, and it is not too
important unless you've severely over-heated the film when using it
(which initiates thermal polymerization). I've left laminated boards
sitting out at room temperature for over a week, and the film still
worked fine later (but they will last longer if you refrigerate them).

There are three layers to the film: there's a clear peel sheet on the
inside, which covers the adhesive part; the film itself, and then the
clear cover sheet on the outside.

I normally go into the bathroom (darkest place), though I turn on a
hall light so that I can see what I'm doing. Cut off just enough
film to cover your board (or as little as you want to experiment
with). It can be tricky to get the inner peel sheet off with your
fingernails, since it is a very thin film, but it is easy with a
couple of pieces of tape. Merely stick the two pieces of tape against
each other at one corner of the film, and then pull them apart. One
piece of tape will be remain attached to the bottom peel sheet, which
will peel away from the film; the other will remain attached to the

cover sheet, which will stay attached to the film (99% of the time). The film may not feel sticky at first, but if your fingers are slightly wet, they will eventually start to stick; so be light on the touch. I normally apply a 2%-5% alcohol solution by gliding my wet fingers along the inside of the film. The alcohol helps to soften up the adhesive, so the film will stick better to the board. You don't want to use more than about 5% alcohol, otherwise you may have trouble with bubbles forming under the film later. After you apply the film to a clean board, there will be so much moisture trapped under it that you will have a few seconds to position the film where you want it by sliding it around the board. After it's positioned where you want it, you can start rubbing the excess moisture out from under the film with a wadded-up towel. The towel helps soak up the solution as it bleeds out from under the film, and also helps distribute the pressure from your hand to help keep the film from stretching too much as you rub it out. Work in all directions, the idea is to get the film so flat that you can see the texture of the copper underneath it--while not getting wrinkles or leaving bubbles in the film. Generally speaking, the less moisture left under the film, the harder the pressure that you can safely apply. If too much pressure is applied early on, you may have a bit of trouble getting the corners to adhere properly (due to the film stretching out). It may take a few practice tries; I've found it easier to start out with small patches of film, maybe a couple of inches square, just to get used to how it works. Having another towel under the board also helps, but make sure that it is not too thick, as you don't want the board to flex too much as you are rubbing it.

If you are using a board that is larger than a few inches square, it is necessary to roll out the film with a rubber roller as a final application step. This ensures that the film is bonded fully with the board, and that there is as little moisture as possible under it. I got a 24" roller from an old defunct typewriter, and it works fine. It doesn't matter where it comes from, but it should probably be made from rubber, since it has a bit of "give" to it. Plastic rollers are usually too stiff to conform the film to the imperfect surface of the board. Place the board on a stiff, flat surface about waist-level, and roll the film out. The purpose of putting it so low is so that you can put your weight into it, in a controlled manner. What you don't want to do is slip, and then wrinkle the film. Go very slowly, giving bubbles and moisture time to work their way out ahead of the roller. When you are done with this, the final step for laminating the film is to bake the board in the oven at 195-200 deg F for 10 minutes. If you see bubbles under the film, then you probably didn't work out enough moisture. For reference, I rarely get them in my boards. Once you get some practice, it only takes about 15-20 minutes to clean and fully laminate a board. After letting the board cool down to room temperature, you are ready to expose the film with your negative artwork. If you choose to use glass to hold your artwork to the board, don't use hobbyist-type glass that they sell in

craft stores. It has UV inhibitors, and multiplies your exposure times. Instead the el-cheapo hardware store glass works the best. But I don't personally use glass, anyway. The reason is that I do fine pitch (5 mil.) traces, and without a vacuum frame, it's darn near impossible to get the glass (and artwork) perfectly flat against the board. So I personally just put the artwork flat on the board, and weight it down at critical points with small coins, screws...whatever's handy...to hold it flush against the board.

A good source of UV (and heat, unfortunately) is a quartz halogen lamp. Tungsten halogen does not work. With a 500W lamp, with the bulb 12" away from the artwork, it takes around 25-27 seconds to fully expose the film. It may vary a bit, but that's a good starting point. Unfortunately, 500 W of heat is seldom good 12" away from plastic film (it wrinkles), so it's necessary to have a type of "shutter", something with which you can expose the film for 2 seconds, then let it cool for a few seconds, for example, before exposing it again. If you have UV flourescent bulbs, then better from a heat standpoint...but I haven't personally used them yet, so I can't give advice on them. But the halogen worklamp is cheap, about $10.00, and they're sold at Home Depot.

So far as developing the film is concerned, first remove the top cover sheet (it's amazing how often I forget to do this). It doesn't develop too well, otherwise. Then add approx. a teaspoon of sodium carbonate to a bowl of warm water to make the developer. Sodium carbonate is an alkaline, and is used to raise the PH of pools. It is cheap, and readily available in pool stores and hardware stores. It is also not caustic to the hands, so feel free to rub the board with your fingertips lightly as it develops, as this will speed up the process. After approx 5 minutes, the board should be developed. If parts of the board that should be bare copper still feel very slick, then you probably have not developed it enough (or have over-exposed it). Feel the resist-covered parts for comparison.

It's getting past my bedtime, here, so I'm going to wrap this up, but I'll finish by saying that when you want to strip the resist from the board after you etch it, merely take the same developer solution, and vigorously boil the board in it for about ten minutes. It will dissolve right off the board. It may help to add a bit more sodium carbonate to the solution, but it will not need much in any case.

Feel free to ask any further questions if needed.

Best Regards,

Sam B.

Prices and quality vary but I generally from QSL in Erith OK.

Typical price is £7.5 / crystal for a 10 day (or so) delivery.

Forgot to say Richard, BE CAREFUL OF YOUR FINGERS. Those crystal cases are sharp when you start cutting them off. Tests showed blood was not as good at lowering the frequency as ink.

No personal experience. But I read in QRP Homebrewer
http://www.njqrp.org/data/qrp_homebrewer.html
that the cheapest way to build a filter is to buy stock crystals for around
a dollar apiece and sort them for characteristics.

Of course, you are severely limited regarding nominal frequency.

Chris
Some ideas
The reset pin should be low for 10 master clock cycles.
I think your suspicions are right about IOUD. From memory I think you should clock this at the end of the 6 byte transfer, not with each byte.
Also, the default for the DAC multiplier is zero - you will have to set this up. See

http://members.iinet.net.au/~richardh/Direct%20Digital%20Synthesizer%20using%20the%20AD9854%20quadrature%20DDS.htm

for some code that works in serial mode

Depends on which radio, or what application, you need them for,
plus a whole host of other factors (holder type, accuracy, etc.) I really
can't give a good answer due to the lack of information from your end.

I will say this much; I've ordered crystals, and recrystalled
channel elements, for Motorola radios from International Crystal in
Oklahoma. Never had any problems with their stuff, and their service has
always been top-notch.

We used to use a KIM-1 that was much like the Motorola trainers. It
was just a motherboard with a numeric keypad that let us enter the
programs in Hex. As I recall the ones we used were before the S-100
buss came out...Then again that was over 20 years ago.

I just took delivery of qty 15 8.8125 MHz xtals produced by
West Crystal in Kelowna, BC, for some MMDS converters I bought
for AO-40 reception.

$10.15 Cdn/each, and they did a great job of matching all
the parameters like capacitance and temperature co.

Their overtones are a bit more pricey than fundamental cuts, tho.

Cheng

Yes, not that bad. I guess the cost mounts up if you
need several crystals though.

I got the following quote from a UK supplier (me being
in UK).

"5.172400MHz HC49/20/30/10/30pF
10 pieces: UKP 5.72 each
50 pieces: UKP 4.80 each
Delivery 15~20 working days following receipt of
order."

That means a 5 pole filter would cost me anout ï¿½28.60
in xtals. I suppose an equivalent commercial filter
would cost more.

>(No, don't have the user-manual, which would
>give me the specs for it.)

Here's how I did it, the line out from the computer to a 25 year old
Panasonic "shoebox" cassette recorder's microphone input.

```
+---------
| mic in
Left --/\/\/\----+ .01 uF V
Right --/\/\/\----+-----||-------/\/\/\--+----
56k ohms (both) 10k ohms |
gnd |
----------------------------------------+
```

The very small capacitor value is to compensate for the huge bass boost on
the input. Given the age of the recorder, I assume that, although it has
a built in electret mic, the external input was for a dynamic microphone.

I just came across an old "Rat Shack" Science Fair project. It's a "Three Transistor Short Wave Radio". Tells you how to wind the coil(s), how to hook it up to an amplifier, put up an antenna. It has regeneration for the SSB/CW stations. By winding different coils,it'll tune 4.5-7, 6-10, 9-14, 13-20, 19-28, and 26-50 Mhz. Whole thing is 6 pages. If you're interested, let me know and I can xerox the whole thing. I have no access to a scanner so can't send it email, sorry! Only hard part is the 365pf capacitor. Eric KA6USJ

Thanks to both for the replies!

I indeed had the multiplier not powered down / bypassed. Now I turned it off, and even loaded 0xFF's into both multipliers and freq tuning words (like in your source code too). Also tried pulsing the update clock only once, after all freq & multiplier data was in the buffer memory. Tried "digital powerdown" both in on and off. But the chip still doesn't give out more than low-level DC... :-(

Ok then I tried to read back the written and "transaction committed" register data. The control register stuff I read back corresponds precisely to what was written into the registers. Fine till now. But all the freq words and multipliers which are read back are zero!
Does that sound familiar? Any ideas? Are these registers not supposed to be read back?

Btw, Richard, I think there's an error in your DDS source code (at least in the one on your site):

```
ldi temp_1,0b00000001 ; QDAC source internal,mode 0 (single tone)
; freq update external
rcall DATA2DDS
```

The AD9854 datasheet says the last bit should be low/0 for external, and high/1 for internal update clock generation (page 21, datasheet revision B). So you should be writing an 0x00 to use the external clock.

sigh now I'm off to check the PCB board for errors, for the umpteenth time. Maybe the AD9854 is half-dead...

I'd still be grateful for comments on what could be going wrong here...

thanks,
- Jan

Well I have been and it's been okay. Today the subject
was crystal filter design and for some reason thought
sci.electronics.design was the place. But then I
thought, some folks at rec.radio.amateur.homebrew would
probably know all about design and I need not bother
with sci.electronics.design.

Rich.

The problem is that you are specifying a weird frequency. If you could move your IF to 4 MHz, you can use cheap surplus microprocessor crystals, which typically run US$1 or so. You have to match your crystals for frequency (obviously), and you may have to play some impedance-matching games.

The pencil lead is for when you grind a bit too far, and you need
to put a bit back. Or if your crystal is a tad too high in frequency,
and you need to go lower. If you added too much lead, it would affect
the crystal in more than frequency. Of course, you could always
erase it, unlike when doing actual grinding.

People don't think about grinding much since crystals are in sealed
mounts nowadays. You'd hear about grinding crystals far more often
back in the days of FT-243 crystal holders, where you could easily unscrew
the cover if you needed to do something to the quartz.

Though, thirty to thirty-five years ago, a guy named Larry Walrod in
BC wrote a number of articles for CQ magazine, where he was grinding
HC-6 cased crystals. He gave details about opening them (using a heatsink)
and he claimed he had no problems once everything was back in place. He
even had a jig so he could test the crystals without actually
soldering the cover back in place.

He was doing intriguing things with those ground crystals. Direct
conversion SSB transceivers, with the crystals on the signal frequency.

Message-ID: <Oqwba.5843$Ja6.5304@fe06.atl2.webusenet.com>
Source record: 36998

If there is a better (or more appropriate) NG to post these questions please let me know.

After 8 years in the hobby I've finally decided to address GROUNDING. About all I know is equipment should be grounded and
everything in the house (including house electrical) should have a COMMON ground. Well, the shack is at the opposite end of the
house electrical ground. To couple the house electrical ground and a shack ground rod would require a trench approx. 80' long ...
it's not going to happen soon so I'd like to address just grounding what I can for now.

I am wondering exactly what equipment SHOULD be grounded
Equipment is as follows:
(1) HF transceiver(100w)
(1) HF antenna tuner
(2) VHF-UHF transceivers
(1) TNC
(1) 12v pwr supply (astron 35M)
(1) RigRunner power distribution block
(1) tabletop scanner
(1) PC used for digital mode operation

All above items (except PC) are powered from the one Astron pwr. supply
All radios above have different antennas
The PC and Astron are on different house AC circuits
(you may not need all this inf., please disregard what is not necessary)
If there is a web site with the appropriate information the link would be appreciated!

I would like to know what equipment should be grounded, ground wire sizes (for example; is 18 gage wire on the HF rig enough; is
18ga. sufficient for the TNC if the TNC should be grounded etc?

Would it be OK to have a 8' ground rod outside, coupled to the shack ground, even though it is NOT coupled to the house electrical
ground? Is 8' enough ... I can get a 10-12' rod if necessary? Is copper clad iron OK or should it be pure copper rod?

Is it OK to couple the common ground in the shack to the house wiring AC ground?

Also, I have heard certain metals are chemically reactive when touching (e.g. certain alum & copper)
but those are the only ones I'm familiar with. Is stainless and or steel (iron) ok to use with copper?

Lot's of questions I know, but any helpful information would be appreciated!

Vic / KE4QJK

Hello all,

I have an Avantek Y085-2217 2-8GHz osc. and would appreciate some help with some questions.

1) Main Power -5v, +15v - do these have to be sequenced I.E. -ve power before +ve on power up, remove +ve, remove -ve on power down.

2) HTR - any idea of nominal supply and warm up time ?

3) Tune - +ve or -ve tuning current ? 500mA seems typical. What is the initial freq with no current applied - Low, mid or High Freq ? What happems with -ve current ?

4) FM - Presumably fine tuning on 'Tune' but with lower inductance so higher agility ??

5) RF power level +5 to +15dBm seems typical, is this about right ?

A data sheet would be wonderful.

My direct email is markaren1 at earthlink.<nospam>com remove the <nospam> and replace an at at the at.

Thanks,

Mark.

> After 8 years in the hobby I've finally decided to address GROUNDING.

There are three reasons to ground:

1. To reduce shock hazard from the AC mains.
2. For transmitting/receiving.
3. For lightning protection.

#1 will be taken care of if you use the now-standard three wire AC plug and your house wiring itself is properly grounded. The length of the ground wires in the house is of little consequence, within reason. All of your equipment which has a metal case or which has metal parts connected to the circuitry (knobs, etc) should be connected together and connected to the "third wire" AC ground.

#2 Should not be done at all, IMO. Your RF energy should not be traveling through dirt. Get it up in the air where it belongs. Good antenna systems do not need "grounds".

#3 Lightning protection. The PolyPhaser web page has a wealth of information, especially this article specific to ham radio:
http://www.polyphaser.com/ppc_PEN1016.asp

Hope that helps. More questions?

1902. Re: Anyone have experiece of ordering custom made crystals?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-12 04:14:03 UTC
From: Jim Pennell <NoSpam@killspam.com>
Message-ID: <b4mc6d$a77$1@slb3.atl.mindspring.net>
Source record: 37005
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design,uk.radio.amateur

When I wanted to build a CW filter, I used 5.000 MHz crystals which are VERY common computer timebase crystals and can be gotten many places at low cost.

The crystal Q was relatively low so I had some insertion loss, but for the price I got a 450 Hz CW filter with about 270 ohms terminating impedance.

So if a particular frequency is necessary, custom crystals might be needed but if you can shift to one of the computer timebase frequencies then the crystals are low cost and easy to get.

I think that's a significant point. Amateur crystal filter building
has pretty much always relied on a source of cheap and available crystals.

Forty to fifty years ago, it was military surplus crystals in FT-243
crystal holders. There was lots of channelized operation in the military,
so one could find plenty of adjacent channel crystals that were space
just right for a filter. The norm was a lattice filter of some sort,
so the crystals needed to be spaced apart. And since you could unscrew
the crystal holder to get at the quartz, you could grind the crystals
if you couldn't get the needed spacing at the desired center frequency.
At first, they'd built them at 455KHz, but then they were in the HF
range, often at that ubiquitous 9MHz.

Yet, the need to grind and/or find closely spaced crystal sets was
always a sore point. Homemade crystal filters seemed to disappear
almost as soon as commercially made HF crystal filters were available.

But then when people started writing about ladder filters, it
restarted homemade crystal filter building. Since the ladder
filters needed crystals on the same frequency, it made getting
crystals easier. Though, the scheme counted on cheap crystals so
you could buy a large quantity, and sort out enough with matching
center frequency and other characteristics that were good.

But in either case, when building it was relatively easy to adapt to available crystal frequencies. If you couldn't get 9MHz crystals, then there were always 8MHz crystals, though of course there were some issues that had to be dealt with, such as getting the right bandwidth at a given center frequency, and troublesome spurs.

Modifying a rig is another matter. You have no choice about the center frequency, since you are trying to fit it into an existing rig. And the chances of getting crystals, especially cheap, at a given IF, go way down.

Having crystals made up may then become the only choice, depending on the specific IF. And the more specific the specs of the needed crystals, the higher the cost. Loosen the specs, and you may need to buy extra crystals to get enough that are suitable. Either way, it's going to more expensive than using available crystals.

That's probably the old FT-243 crystal holder...plate comes off
the wide side. If the plastic case separates and comes off in
the direction on-line with pins but in opposite direction, it would
be the old FT-241 holder.

About 30+ million quartz crystal units were produced by USA
during a three-year period of WW2, roughly a million a month.
No man-made/-grown quartz then...nearly all raw quartz
imported from Brazil. :-)

I didn't know that he'd written such an article. The scheme
is also known as the Weaver method.

It does use phase shift networks, just not in the signal path.
Split the audio into two mixers. The mixers are fed with
an audio signal (commonly 1800Hz), but the feed to each mixer
is 90 degrees apart. The output of those mixers are fed
to two more mixers; again, their oscillator feed is 90
degrees apart. This second oscillator would be at the
IF frequency, or even the signal frequency. One way
of looking at that first set of mixers, admittedly simplistic,
is that it forms a broadband audio phase shift network. Of
course, it's not so simple because of that carrier right in
the middle of the audio passband.

A limited bibliography on the subject is below. Admittedly limited
to what I've come across, and I think Wireless World
and perhaps QEX have had additional articles on the subject
in recent years.

QST Sept 1957. Howard F. Wright. "The Third Method of SSB".
(This seems to be a popular version of the IRE article, complete
with some excerpts. Note, it says the Dec. 1956 is by D.K. Weaver,
which makes sense since it is called the Weaver method.)

New Sideband Handbook. Published by CQ in 1958. Don Stoner.
Two pages at the end of the phasing chaper cover the Third Method.
A block diagram, and details on a commercial transceiver using
the scheme.

CQ Oct. 1962. An explanation, including a block diagram in
the Sideband column on page 56.

CQ June 1965. Fred Johnson. "The Third Method -- Is it Worthwhile?"
(A more extensive explanation, with the diagram from the IRE
article, it was also in the QST article, that lacks component values.)

The Radio & Electronic Engineer. March 1973.
I've never seen this article, don't even know the magazine, but
apparently there is something about the Third Method, maybe as
a receiver, maybe with AC coupling between the first set of
mixers and the second set.

The fifth edition, 1977, of the RSGB Radio Communication Handbook has
some mention of the scheme. In the receiver section, briefly, and
HF Transmitter chapter. No construction material.

Ham Radio Jan 1978 VK2ZTB "Ssb phasing techniques" This is a review
of various schemes, and memory tells me there is a bit about the
Third method right at the end.

Electronics World + Wireless World April 1993. Nic Hamilton. "SSB: third
method, fourth explanatiion" (An explanation, and a full circuit
in solid state taking advantage of digital circuitry.)

QEX August 1991. Peter Anderson. "A Different Weave of SSB Exciter"
I'd say more of a construction article than explanation, though
it has that, and again making use of digital circuitry.

I guess I should clarify that bit about digital circuitry. No digital
processing is done in either of these articles; the digital is
in the quadrature oscillators, and using CMOS switches for the
mixers. But, I gather some have used the Third Method with
a DSP, and there might perhaps be an article about it.

William Sabin's book about SSB may have something about the
scheme; at least, the Wireless World article references something
in it.

These are the references I have handy. I really get the feeling
I've seen some passing references in magazine articles about direct
conversion receivers.

Doing a websearch is going to turn up some material.

ISTR the 10X case Jim, from memory about 1 inch by 1.5 inches and 4
screws with the xtal held by a couple of spring steel plates. There were
(are) others but the 10x seemed the easiest (largest) to work with.

Very interesting, but what does that have to do with anything but C-64?
Why the other items in the title when they are unrelated?

Thank,

Not really - it's in the nature of amateur radio that we pick up knowledge as and when we need it.

Grounding is certainly one of those areas where you can go for years without really having to think about it, if you're lucky - or you can meet big problems as soon as you go on the air.

Also, since "no grounding advice is universal" (ARRL) you're likely to keep on meeting different faces of this problem. After 40 years, I still am.

>Anyways, you can start here:
>http://www.arrl.org/tis/info/grounding.html

Thanks - a very good link.

What's tending me to stick to the odd crystal frequency is that if I change RX 1st IF (say to 5Mhz) I have to mess with the TX C.O. and SSB filiter. That has to go to 5Mhz. This because I was wanting one VFO to control both RX and TX. If the TX had more than one mixer in it I probably could just have compensated by altering a xtal in a heterodyne ocs, but I cannot do that. Other way is to use a sepearate VFO for RX and TX. That means building 2 VFOs.

In that case, it might be better to change the C. O. frequency and SSB filiter in the TX. And make TX crystal filter with cheap 5 Mhz xtals. But then again if the SSB filter was in 5000 Khz, C.O.would have to be on about 4998.5 Khz. Well here we go again, an odd frequency. But could I pull a 5Khz xtal to 4998.4 Khz? That way I could use 5000 Khz xtals throughout. In both RX and Tx.

But, there is a problem with the RX. If my CW/SSB filtering takes place at the 1st IF, I need to build a 5000Khz SSB filter. Easy peasy. But for CW I'd have to build a xtal filter centered on 4998.5 Khz. How do I do that with 5 Mhx xtals?

Thing is, recently I crossposted to three groups. I
bet normally I need only post to rec.amateur.homebrew.
(Although some folks on uk.radio.amateur and
sci.electronics.design seem to know something about
radio) :c)

1913. Filter at 1st IF? (not 2nd)

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-12 10:43:11 UTC
From: Richard <nearlynews_email@ntlworld.com>
Message-ID: <b4n2sp$2129sc$1@ID-150848.news.dfncis.de>
Source record: 37016

Following was written (over at sci.electronics.design)

Plan 2 is the better one, isn't it?

Hi

Your post has got me thinking about changing my design plans.

Perhaps I ought to explain first what I was going to do, but may abandon for new plan # 2.

The RX is double conversion, quite old (mid 1960's) . It's meant to be for CW and SSB, but really everything is geared towards SSB. Selectivity is accomplished at 455 Khz where the bandwidth is about 3 Khz. I am wanting to modify it in various ways, to have a CW filter and a narrower SSB filter at 455 Khz, and to arrange for better VFO and digital readout. VFO to control Rx and seperate TX. I want VFO to read correct frequency going from CW to SSB and vica-versa.

The 1st IF is notionally centered on 5173.9 Khz. However the carrier of course is not here but about 1.5 Khz away at 5172.4 Khz. The 1st IF is nothing but two LC resonant citcuits, so passband is wide. Thus selectivity is acheived at 455 Khz. However it's so wide at around 5173.9 Khz that you get cross mod in the second mixer. Solution: place a crystal filter in the 1st IF to stop the cross mod. But of course, you could not put a 3 Khz wide filter here centered in 5173.9 Khz, because (unless you are willing to alter your VFO and thus alter your frequency readout) a CW signal on 5172.4 Khz is out of the passband. So is the SSB carrier, but of course that is okay for SSB. So, what you do is put in say a 6Khz filiter and that way you have no problem attenuation the CW signal. You then put seperate CW and SSB 455 Khz filters in and things are fine, remembering to put in another xtal in the xtal osc for the 2nd IF so that you can centre a CW signal at 455 Khz, otherewise it would land at 456.5 Khz.

This would work, but you got me thinking about something possibly better. If you can get the

crystals, there is no reason why the CW and SSB filtering should take place at the 1st IF. What you do is construct two filters, a CW filter centered on 5172.4 Khz and the SSB filter centered on 5173.9 Khz. Changing from CW to SSB requires no change of VFO. If you kept the old 455 Khz filter in you would have to put in another xtal in the xtal osc for the 2nd IF to get the CW signal away from the skirt, but if you took that filter out and the 455 Khz IF was pretty broad, then you could probably get away with not having another crystal for CW working.

Plan # 2 I think is the best one. What say? But it is dependent on building crystal filters at these odd frequencies. Which has to be, unless I start messing with the TX crystal filter and C. O.

> with the TX crystal filter and C. O.

Actually, if I was prepared the change TX C. O, I'd
have to have the C. O. at 4998.5 Khz and I'd make a
5.000 Khz SSB filiter. Could I pull a 5 Mhz xtal to
4998.5 Khz?

On the RX side I'd make a 5000 Khz SSB filiter, but the
CW filter would have to be 4998.5 Khz. Could the CW
filter be made with 5 Mhz xtals?

(All because I was wanting one VFO to control both TX
and RX).

I don't have info on that P/N but have some info on other Avantek
YIG oscillators that are probably similar.

>
>1) Main Power -5v, +15v - do these have to be sequenced I.E. -ve power
>before +ve on power up, remove +ve, remove -ve on power down.

As far as I know it doesn't matter. From specs on units I have its
probably about 200-350 mA on +15 V and 60 mA on -5 V.

>
>2) HTR - any idea of nominal supply and warm up time ?

Don't know the time, but you can use them without connecting the
HTR. Should be connected for stability, though. Probably wants 20 to
28 VDC at about 1.5 to 2 Watts. I think it should stabalize pretty
well in a few minutes.

>
>3) Tune - +ve or -ve tuning current ? 500mA seems typical. What is the
>initial freq with no current applied - Low, mid or High Freq ? What
>happems with -ve current ?

Its a coil. Current through it determines output freq. The similar
units are 20 MHz/mA so 2-8 GHz would be about 100-400 mA. If current
is too low or too high it won't oscillate. Spec may be 10 ohms in
series with 95 mH.

>
>4) FM - Presumably fine tuning on 'Tune' but with lower inductance so
>higher agility ??

Usually used for phase locking or FM modulation. You can use without
this. Specs for units I have are all 310 kHz/mA. In addition to
finer control, you can also control this coil with a higher
frequency modulation than Tune. Spec may be 1 ohm in series with 1.7
uH.

>
>5) RF power level +5 to +15dBm seems typical, is this about right ?

Three units I have specs for with 2-8 GHz range have nominal outputs
of 14.8, 20 and 23 dBm so its probably one of those. Output may vary
by 5 or more dB across the frequency range.
>
>A data sheet would be wonderful.

I gave you most of the important stuff if the units are similar. You
should be able to hook up DC voltages and put an adjustable current
source across the tune coil to see if it works. Should be safe to
try and you can then tell if the tuning currents match by checking
output power/freq.

> Does that sound familiar? Any ideas? Are these registers not supposed to
> be read back?

Miraculously solved!

a) weak solder paste joints on both I/I2 pins. Exactly _these two_ out of
all 80 possible pins - maybe I should try the lottery this week! ;-)) The
pins conduct when the scopemeter probe is pressed down, but are open-circuit
otherwise, i.e. very nice to spot that...

b) register read-out started working all by itself overnight. Maybe it was
helped by shaking the 12V battery, or a neutrino striking at the right spot,
or something similarly likely and probable.

But, finally, the filters now put out two wonderfully crisp sine waves! 8-)

thanks,

- Jan

hello...

can anyone tell me what polarization ,vertical or horizontal) when looking into a typical 10ghz gun oscillator unit (ie sofan doppler unit,) with the gun diode vertical, connections on top, longest side of waveguide horizontal I will be getting???

Also on your typical lnb ie amstrad blue cap vertical or horizontal polarization when supplying 13V NOT 18v to the LNB...

modifying blue cap to transmit and i need to know which fet to install in output stage h or v..above questions will answer ..using same + sat can to rx.comparing against dopplar unit for range and drift.

thanks simon G0zen (dont you find the more one learns the more one discovers that you know nothing.)learning about microwaves the hard way...

Hi Rex,

Thankyou.

Main tuning - is this intended to work with bipolar current (+- 200mA)
or unipolar ? 0..200mA ? Looks like it's unipolar from the way you
phrase your reply.

Regards,

Mark.

Hello Harold

I don't know if you have been following my frantic threads, scattered everywhere, on xtal filters etc, but I feel almost in a spin as to what do with modifying a FR50B FL50B set-up.

A mod article said put in the first IF of the RX a surplus type 5200 Khx ztal filter and suggested SEI QC1246AA or QC1246AC. These are narrow filters, perhaps 2.7 Khz to 3 Khz BW. Problem is that such narrow filters will put a spanner into the works of my intended other mods. Why, because a narrow 5.2 Mhz xtal filter would in fact be centered on SSB audio, not on the carrier. So, switching over to CW the CW carrier (same frequency as SSB carrier) would be attenuated, because the carrier as we know is to one side of the SSB centre frequency. This does not matter with SSB because we inject the carrier by way of BFO.

I wanted the TX and RX to read correct frequency, I do not want to have to retune 1.5Khz to place the CW signal into middle off a filter passband.

So I eventually figured I'd need something like a 6Khz filter in the 1st IF.

Rich.

Send me some email with specific questions, I might be able to help. The point about IOUD being an output on default is important. The 1st routine in my code is called "own_IOUD" where I take control from the AD9854.

If all you do is write to the frequency register, you should get an output.

Of course, I would love it if you purchased my DDS8m for a "known working" AD9854 example.

Steve.

You might want to read up on modifications for the Drake R4C
receivers. They have a first IF of 5645kHz, and were originally
equipped with a 12 kHz filter following the first mixer (additional
selectivity came at later stages). That filter is too wide and
has broad shoulders. This is aggravated greatly by a relatively
poor 2nd mixer stage design.

You can find all manner of interesting discussion about the
merits of replacing the filter with a very good 8 kHz filter
(wide enough to allow the noise blanker to work), a 6 kHz
filter (best for ssb, but it does impair the noise blanker),
or a 600 Hz filter (best for CW). Also there are discussions
about various modifications to improve the design of the 2nd
mixer, all of which you'll find interesting too.

It should be noted that out of the box a Drake R4C was not a very good performer, but with a number of modifications it is one of the best, and arguably the best, receiver available in terms of sensitivity, dynamic range, and overload characteristics. Hence the modifications for it are worth researching as an example of good engineering.

The original I.R.E. article was indeed by Weaver, and
the December 1956 issue is entirely about SSB. I found
it in the University of Toronto library and spent a
pleasant afternoon reading it from cover to cover.

S53MV has published a collection of radios based on
the same basic layout that he calls "zero IF", but
are Weaver/3rd method by any other name.

There was another Weaver design in RadCom (RSGB)
circa 2000.

Since all you need is a quadrature audio signal and
two very sharp low-pass filters, this method lends
itself to a very simple DSP implementation. The build-
ing blocks have all been published, many times, in
many forms. What are you waiting for? Go get them!

1925. GUF-1 8 pole filter: Specs required

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-12 19:23:43 UTC
From: Richard <nearlynews_email@ntlworld.com>
Message-ID: <b4o1ec$1smp14$1@ID-150848.news.dfncis.de>
Source record: 37029

Hi

Can anyone supply me with the specs for this filter, detailed
specs if possible.

(Might try to copy specs with homebrew xtal filter)

Thank you.

Rich.

From your description of the waveguide orientation, you will get vertical
polarisation.

Not only will these guys make small quantities, they are absolutely great. They will make you whatever you want, and if you don't know what you want (probably you don't when it comes to the gory details of crystal parameters), they can help you figure it out. They are not terrifically cheap (figure $15-20 a crystal or so for very small numbers), and they are not
fast (at LEAST a 2 week wait), but they will make sure you get *exactly* what you need.

To tell the truth, after seeing your need to keep a specific IF, I would probably call International and tell them your story. You will probably pay the high end of their price, but if you get 5 crystals from Joe Blow crystal manufacturer, they are NOT going to be matched. You will want 20 or more crystals to get 5, and for that you want to be using a frequency where you can pay a buck or less for a crystal. International will get you crystals that are close enough for your purposes, and they probably will help you choose specifications that don't result in paying too much.

Another thing about ICM, they actually test before they ship, and once in a while they will test your crystals and they will fail, so there could be a longer delay as they go back and re-manufacture your crystals. So while they usually take a couple of weeks, and they will tell you exactly the schedule, once in a while you will get a call that you will need to wait a couple more weeks, but in my experience, that is pretty rare. The good news is that they tend to keep you informed.

>phrase your reply.
>

Yes, it is a unipolar current. The (+) goes toward the positive
voltage and (-) toward the negative (usually ground). The intensitiy
of the magnetic field passing through the YIG sphere determines the
resonant frequency.

I'd suggest, hook up an adjustable current source on the tune coil
and ramp it up slowly from zero. If the specs on your unit match
what I have documented, I would expect it to start oscillating
around 2 GHz when the current is about 100 mA. As you increase the
current, the frequency should go up until it stops oscillating
somewhere near 8 GHz or 400 mA.

I'd measure for power output first and be sure your counter can
handle the output before measuring frequency.

Hi Max,

Thanks for the pointer....I was cleaning out some stuff the other day and came upon this instruction manual(?). Has the schematic, how to operate, etc. It was done in one of their old "P" boxes (for push-in terminals?). Two transistors are used for audio and the other is used in a high gain detector. It doesn't actually mention SSB reception, but does CW. Also needs a crystal earphone. I just might try building one just for giggles. Somewhere around here I do have an old high impedance headset that would probably work with it.

Again, THANKS!!! Eric

Dan:

I have a "yellowed" copy of Weaver's original IRE article from Proc IRE.

Norgaard did write a "repise" article about Weaver's "third method" in
QST Magazine a few years later.

If you are interested, send me an email and I'll go make a copy of the
original Weaver article and send it to you.

I saw a posting by Michael on the thread about the write up on Weaver's
method in Don Stoner's [W6TNS] old SSB book. Wow... that's where I first
heard of that third method myself from Stoner's "New Sideband Handbook
which I bought for $3.00 back in 1958!

This method is/was the first widespread exposition of the use of what today
is called Quadrature Amplitude Modulation [Really should be called
Quadrature
Carrier Modulation or QCM] which is the most general way of generating
modulated
waveforms. A QCM modulator can be used to generate all types of modulation
from AM to SSB to VSB and ISB and FM, etc...

The earliest mass use of QCM was the NTSC [Never Twice the Same Color]
North American color Television system. Today most all modern data modems
use some form of QCM, even the DMT [OFDM] systems use QCM on the
individual frequency "bins".

And... I believe that Weaver [He was at MIT at the time...] was the first to
expose these methods to the general community with his now celebrated
"Third Method of Generating SSB" paper.

This thing of making xtal filters is certainly a shakey affair in some respects. First of all you need a filter spec for the purpose you want the filter for. Well this is a all a bit nebulous to me right now, but (under plan #1) I'd say I need specs simalarish to GUF -1 8Khz, 8 pole filter. Okay, once you nail down your filter spec you got to build the filter. Well, in the end you have to specify xtal parameters. Well, how do you end up getting the right xtal specs. I mean sure, you can mess with a filter program (I just bought AADE filter software) and come up with some xtal parameters if you mess around with the parameters, and send them to the manufacturer, but the specs might be silly (impractical) xtal specs even though xtals of that spec would in fact produce the filter you want. But I think the practical way, is to seek some specs: you need some specs from the manufacturer that will be in the ball-park to produce the filter specs you are after.

But, some manufacturers might not be as experienced at offering specs as others. I was given some specs today in relation to xtals the subject of a quote, but actually, I think they are wrong. The specs will not make a filter with anywhere near 5Mhz center frequency; let alone required BW, stopband attenuation etc etc. In fact I only got 3 out of the 4 parameters I need for the filter program.

Talking to a xtal manufacturer who can give you his xtal parameters and who knows likely xtal parameters that will do the job could be very important.

Alternatively, you just order some xtals of the correct frequency
and hope the filter turns out okay.

Rich.

I used to use a spray-on photo resist made by Electrolube.
I'm not sure of the product number, I think it was called RP50.

Cork the sactimonious rhetoric: Antennas and grounding are two of the three most important parts of any radio system, the third being the actual radio. Anybody who didn't learn that much while studying the Radio Amateur's Handbook (or other appropriate educational resource) for his/her license shouldn't have passed the test. Even if it didn't really sink in (i.e, passing the test by memorizing the answers to the question pool), he has had eight years of jawing on the box to discuss the issue. And isn't that one of the primary purposes of Amateur radio, to "advance the art of their hobby" -- or wasn't that part of the question pool?

Shame on ME? Hell, I'm not even a ham -- I'm a CBer!

When you get to be in charge of the tests, you can flunk anyone who
doesn't understand grounds. In the meantime, I suspect this gentleman,
like a lot of us, thought he *knew* about grounds and later on realized
there was still some more to learn. Perhaps we should just take him out
back and shoot him?

In any event, please cork the put downs for some one who is asking honest
questions and trying to learn something. Better yet, focus on your
fellow CBers. Now there's a target-rich environment!

Source record: 37040

Put my ideas on http://home.online.no/~la8ak/10a.htm

it has been described in VHF communications 20 years ago, and was
modernized 10-15 years ago

I don't care the least if it is too complex for somebody. I often
receive complaints that my circuits are too complex, the only thing I
care for is reliability. Have never had any problems with mastmounted
pre-amplifiers on 2m, 70, 23cm, while it is quite common to burn out a
pre-amplifier, but I don't see the point

1943. IC-V8000 Serial cable trouble

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-13 03:36:44 UTC
From: Woody <KZ4AK@MUNGED.att.net>
Message-ID: <3E6FFCD5.D5E3F55C@MUNGED.att.net>
Source record: 37046

Please Un-munge return email. Sorry, getting scores of spam a day
now.

Hi All!

Just got new Icom V8000 (no mods) and programming software. The $35
cable (DB9 - 1/8" Phone to Radio) seemed a truly poor value for a
homebrewer. I didn't order, but built one. Assuming shaft ground, I
looked at the tip & ring at the V8000 with a scope. On turn on there
was a burst of data from the "tip" line - Ah! Tx out from the Icom.
The ring was steady at +5v - Ah! the RX line. Simple, made cable -
Tip to DB9 pin 2, Ring to DB9 pin 3, shank (shield) to pin 5.

Not so simple! Ran clone/pc software. All that can be user defined is
the com port number. Set to com1, used com1 DB9 on PC (port works
fine to control the K2 rig when running MIXW2 software). The Icom
software could not find the rig. It returned a window telling me to
check com port setting, cable, etc. Tried jumpering/open RTS/CTS at
DB9. Also, knowing (hoping this one) that most '232 ports are pretty
tolerant, reversed Tx/Rx, then back. Same error every try.

V8000 does display "CLONE" nothing else happens on that side.

Grabbing at straws, tried all other port selections with the same
effect. Nada!

Any suggestions?????

Thanks & 73,
Woody

When I worked at Icom the cloning cable was connected , clone out of computer to the ring and the sleeve was ground. The tip is not used for cloning and left open in the cloning cable.

I never supported the V-8000, it came out after I left however if the cable Icom suggests is the OPC-478 with no fancy adaptor then its just as I described. If you ask Icom they used send you a print. Look at the print you will find my name on it, I drew it using orcad a few years ago. Good Luck.

I spent about a month tearing my hair out (what little remains of it) trying to get mine working. I got some great support from this newsgroup in spite of my rantings. In the end it was a programming error in the micro so that the DDS lines were still inputs! Interestingly enough, I had actually checked these by writing a 100 msec square wave to these lines and there had been an output. However at normal data rates they didnt work.
One problem I did find however - is there bus contention on startup with the IOUD pin? I was driving mine direct from a buffer and I managed to damage this input so that I could not update the chip externally and had to rely on an internal update. Remember this pin defaults to ouput low with high pulses when the PLL is working.
You will have to have a current limiting resistor here.
Try powering up the PLL - the current should increase with increasing clock.
What clock freq are you using?
120mA sounds rather low unless you are using a slow clock. At 100 MHz the chip will use about 300 mA and 500 mA at 200 MHz without the comparator or sinc filter. IOUD should put out pulses at 1/10 of the clock (I think)
If you have managed to program the control registers but nothing else, maybe one of your address lines is wrong - I ended up checking every single pin on the chip!
One other thought - is the data you are reading out of the control registers the default values? Try changing all of them and reading them back.

That sounds like an interesting issue; it reminds me again that it
would be neat to see the ARRL put together CDROMs on given themes,
just as they used to have books collecting articles on selected
themes (and still do, though they don't have the feel of the old
books). Get permission to reprint the issue, and put it on a disk
along with important SSB articles from QST (and Ham Radio, since
they seem to have the rights).

Norgaard did have articles with similar themes in QST, actually 8
years before the IRE issue. "A New Approach to Single Sideband",
June 1948, which covers phasing in transmitters and
"Practical Single-Sideband Reception" in July 1948. I have
no idea how those articles compare with the IRE articles.
Both QST articles, though under titles almost like those
IRE titles, are in both the first edition (1954) and
fourth edition (1965) of the ARRL's "Single Sideband for
the Radio Amateur" and the transmitting one is in the fifth edition
(1970). Likely in the other editions too, but I don't have them to check.

The May 1948 issue clearly sets the stage for the articles in
the next two month's issues. He has an article "What about Single
Sideband" in that one, which is an introduction to the topic,
and it's reprinted in all three editions of the ARRL's SSB book
that I have.

You can use a single crystal oscillator with two buffers to feed two mixers to move the IF to a convenient frequency, filter it, then move it back. It requires good shielding, but it will work.

Actually, that would be channel 13, as well as 1750m, and VLF from 5
to 9 KHz, places that most appliance-operating hams don't have the
first clue how to work. I am quite content with these bands (that have
been made usable only by the efforts of radio experimenters, many of
which happen to operate outside of your fraternity). Recently the
hammies have been trying to grab 1750m for their own, and if that's
any indication of the future, I'm sure you frat boys will try to annex
any other usable spectrum space just as soon as radios are
manufactured for them that include an instruction manual. But fret
not, there will always be us unlicensed pioneers blazing a path for
you to follow, and you don't have to worry about me taking a step back
and joining your little party.

Well then you sure have a lot of licenses to pull if you want to keep
the sainthood status of ham radio -- in case you haven't noticed there
are a WHOLE LOT of very rude hams. So before you start dictating your
morality on those without licenses maybe you should clean up your own
camp, first.

Certainly isn't very simple. Almost voodo...

Well, ok, actually the I/O interface of the AD9854 is quite reasonably designed IMHO! At least the parallel I/O one - it took me "only" four hours programming and debugging in total to get the AD9854 into a working state.

Serial looks much more dreadful. Parallel I/O seems the easiest and fastest way to go (no pun) - t.ex. no probs with the internal update clock.

> I got some great support from this newsgroup in spite

Maybe, with the buffer chip, the uC pins had enough leakage current between the uC internal input<->output logic blocks, so that the input lines floated up (or down), and then the buffer output went logic high? Not very probable, but just a thought...

> when the PLL is working.

You probably used the buffer for 5V logic (uC) to 3.3V logic (DDS) conversion?

Sometimes a simple ~1k resistor array (block?) is better than a high current line driver or buffer chip. It works in both directions. 5.0V <=> 3.3V logic level "conversion". At least one can't fry anything that way, not without special talents, that is. ;-)

Btw is the fried input the reason you use the internal update clock in your source code? Or just a bug?

> You will have to have a current limiting resistor here.

I'm using a 3.3V MSP430F149 uC together with the 3.3V AD9854, and the update clock pin works without a resistor. There isn't much current flow on the clock line, even the uC pin is set to output and the io clock is outputting too.

But if you use a high current line driver or logic buffer, your resistor advice would certainly be a good idea!!

> Try powering up the PLL - the current should increase with increasing clock.
> What clock freq are you using?

Now that it works, I got a 200kHz test sine out from both DACs, system clock is 4x50 MHz, and total current draw was about 390mA with all doodads disabled. Still quite low, tho. OTOH, low current draw's just fine with me...

The next interesting task is how to calculate the frequency control registers in an efficient manner...

> 120mA sounds rather low unless you are using a slow clock. At 100 MHz the
> chip will use about 300 mA and 500 mA at 200 MHz without the comparator or
> sinc filter. IOUD should put out pulses at 1/10 of the clock (I think)

It's 1/128 of the system clock - at least when I put in 50MHz without the PLL, the update clock was ~390kHz. That'd be 2.3 MHz if sysclock is 300MHz, so it is "slightly" too fast to be useful. It's a futile attempt to use serial I/O at a 2.3MHz-default I/O-clock... ;-)

> If you have managed to program the control registers but nothing else, maybe
> one of your address lines is wrong - I ended up checking every single pin on
> the chip!

LOL! Same thing here - already checked all pins more than twice!
(cf other posting)

> One other thought - is the data you are reading out of the control registers
> the default values? Try changing all of them and reading them back.

The readback works correctly now. Yet I don't have a single clue about why it _didn't_ work with any other register than the control reg initially. Heck, I didn't even change the software.

Many thanks for your comments and help!!

cheers,
- Jan

I guess very long is a relative term. Certainly I have been using mine for 6 months and noticed no adverse effects, in fact the modified crystal performs the same as an un-mutilated one in all respects I am able to measure (drift, crystal activity etc).

Put this in your pipe and smoke it...

You said you wanted a digital readout on the VFO. One way to accomplish this, of course, is to count the VFO, a process typically performed with a PIC or similar computer, which has the added benefit of seriously whacking the parts count to make a display.

Another approach is to synthesize the VFO, which gives you the display, plus added stability, at the expense of a little phase noise. Typically, the synthesizer is controlled by a micro since often it needs weird inputs and again, the micro gives you the parts count advantage for the display.

OK, now, once you have the micro controlling the VFO, "changing" the VFO is only ones and zeroes.

On the filter ... note the discussion on buying custom crystals. Building a filter for an arbitrary IF can be an expensive proposition. If you can choose an IF based on what frequency you can get cheap crystals, in quantity (because you want to match them for your filter) then building a crystal filter can be pretty cheap. But to decide that you want to build a filter for some arbitrary IF means that you will need custom made crystals of the highest quality, unless you are prepared to buy typical quality in several times the needed quantity to do the matching.

An added consideration, especially for SSB, is that steep skirts are easier to come by at 455 kHz than at 5 MHz.

This doesn't make a broad filter at the first IF any less of a good idea, however.

..

1958. Cheap weather data RX??

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-13 12:08:42 UTC
From: tobias_richter_@hotmail.com
Message-ID: <83a39bbc.0303130408.35bc283c@posting.google.com>
Source record: 36910

Hi there

I wonder if there`s a cheap way to build a RX for 4583 and 7646kHz RTTY. That's the frequency for german weatherforecast (for ships) and I want to receive those transmissions. I've got already a program that converts the 50Baud Signal to readable text.
Because of me being just a student and having no money for a Shortwave-RX/TRX I now look for a cheap solution to receive the frequencies. My first suggestions were to use a direct conversion RX with NE612 and TTL-oscillators. But I wonder if it will produce to many intermodulation products by near AM-broadcast stations.
A friend of mine has used a FT847 for receiving test on 4583. The signal was almost 9+30dB at a 21 meter long windom antenna.......
Any suggestions what RX and which antenna I shall use?
Important: It must be cheap! If I get some RX to work I want to build a second one for my school, because I want to get others interested in my geographics class :-)

Tnx in advance de Tobias, DO1NTR

Since it adds two mixers (more things to overload) in the signal path,
another oscillator, and all the various byproducts of the mixing, I'd
only do that as a last extent.

And in this particular case, I wouldn't even suggest it, because it's
going to send things on yet another tangent (and thread) when some
of the basic issues have still not been dealt with.

I feel I must add, don't be tempted to order "rush" crystals!
A good "grinder" will age the crystals, then correct the frequency;
with rush units, as soon as they hit the mark, they're shipped,
and _you_ get to deal with the ageing.

Hi Guys;
I have a few of these blowers which would make great Amp Air Movers :-)
They are made in Germany, may have a bit of dust but look new.
I was unable to test them because I have no idea how to apply the 115VAC, too
many connections for me, Hi!
Here are some links to product info & distributers w/prices.
They cost over $140 each.>>
Medibix Global Component Database - EBM Industries, Centrifugal G2E120 Series S

Browse the Big Book
MSC Industrial Supply Co.
I would like to get $40 ea shipped.
Pics give all the info>>

Depends what you're testing for.

If you're only interested in the breakdown voltage (usually
characterized as 1mA leakage) you can test an MOV with a
variable-voltage DC supply, as you would test a zener diode... except
that you can reverse the MOV and test it with the other polarity too.

If you want to know about the surge-absorbing capacity, you can't make a
static DC test, because those parameters are time- and energy-limited.
You're into heavy pulse technology.

Talk about cheap shots....

> Just curious where such venom comes from.

From hammies like you, Bill. Go back and read my reply to the original
poster again, but this time set aside your contempt. I may have taken
a poke at the OP, but there was no "venom" in my post -- all that
hatred came from you and your attitude that even mild criticism of a
ham constitutes a "cheap shot". Don't get me wrong, there are a lot of
fine and decent hams. But there are just too many hams like you, hams
who think that once they get their ticket that they have automatically
risen above the crowd, that they are somehow better people than those
without a license. Amateur radio isn't a 'club' or "fraternity". It
isn't a military rank where you can dictate the actions and morals of
others with 'lower' rank. It's just a license to operate a radio for a
hobby. Thats all. And it's because of attitudes like yours that many
fine radio enthusiasts are discouraged from getting a license and
going further with their hobby.

Get a clue, Bill. Then get a new attitude.

If it's a mains MOV, apply power through a light bulb. If the bulb lights to full brightness, it may be that the MOV is shorted (but there are obviously other possible causes).

If the bulb is quite dim, and the equipment shows signs of working, short out the bulb and apply full mains power (through a fused supply of course). But even if everything appears to be OK, this test will not tell you anything new about the MOV - it's not supposed to conduct at normal mains voltages anyway, so it could be either perfectly OK or completely open-circuit.

If the MOV seems to be OK, the only way to be sure that it will protect against abnormal mains spikes is to test it at a higher voltage. Do this *outside* of the equipment it's supposed to be protecting! As I said in the previous posting, test for the onset of conduction (DC voltage required to pass 1mA).

If it isn't a mains MOV, the same principles apply, at whatever voltage it's supposed to operate.

Hokay people, let's hold fire on some of this.

After working with electrons, fields and waves for more than a half century, I'll reveal some secrets that most folk learn but a few have forgotten:

Electrons, fields and waves don't respect human emotions, human regulations, human opinions, human-anything that doesn't correspond to Laws of Physics.

That's the only Law that electrons, fields and waves respect.

Electrons don't respect anything about pretty certificates or other pieces of paper except for the paper's conductivity and/or dielectric constant. That paper includes money, stock certificates, license forms, and anything else from an "official" or unofficial source.

One can cajole, wheedle, threaten, curse, shout, entreaty, pray to electrons, fields and waves and they won't pay no never mind. They won't care of somebody says method X is "better" or "blows away" method Y according to what someone wrote in QST or Popular Communications or whether it is "supported" by some human organization.

Electrons, fields and waves do their own thing according to Laws of Physics. To avoid going SK too early try to figure out those Laws before pinning on some chicken inspector badge. The life and wife you save may be your own.

But if you provide a couple of kHz tuning for said oscillator... voila!

Band Pass Tuning.

... and USB, LSB etc is just a matter of switching a few presets that set the PBT to the right place.

Huh?
I thought the whole trick in modern crystal making was a
quartz plate with the conductors plated and premounted
in the case base and made in ranges.

Then, when the customer names a frequency, you edge grind it
well away from the conductors to bring it up to frequency and
then bang the lid on. All the aging in the conductors
and the mounts having already happened and all that double
handling cost is saved.

Am I out of date already?

Ian,

My assumption is that you are talking about transmitting. You won't necessarily have problems 5 meters above your ground rod at HF. You are most likely to have a problem if you are one or one-half a wavelength above ground. Just like one normally doesn't use an antenna with even wavelength multiples.

If you want an "artificial" ground for transmitting, the easiest circuit is a counterpoise. It's just a quarter wavelength piece of wire connected to your transmitter ground. Lay it out on the floor. It can go around the perimeter of the room. Not recommeded to touch it during transmit! Also don't recommed high power. But it should be fine for 100-150 watts or so...

>Does anyone know where I can find a circuit for an artificial ground.

The ones I've seen are series LC circuits with a rf ammeter. They are used to try and tune out any reactance you may have in your ground system. You tune for maximum rf current in your ground wire.
In your situation, a 1/4 wavelength piece of wire connected to you rig's ground will provide an rf ground, but only on the frequencies that the wire is an odd multiple of 1/4 wavelength.

Seems like a practical way to me.

Semi-custom with a little tweaking is going to be less expensive than
total custom work. Doing the bulk of the work ahead of time makes
sense as well, to allow quick turnaround.

Happy trails,

There is still some mileage in sticking in a broad filter in the
1st IF, and doing the main filtering at 455Khz. I've been trying
to find a filter parameter to aim for and someone mentioned
filters for the Drake R4C series. Well, the RX uses a 1st IF of
5645 Khz not that different from my RX 1st IF on 5172.4 Khz.
Eventually I've hit paydirt and found the filter specs of a
replacement filter fot the R4 series. It's here:

http://www.qth.com/inrad/r4c-1if.htm

I may try to copy the specs with a homebrew filter, except of
course the centre frequency.

>Am I out of date already?

"Aging" in quartz crystal units is a specification more
suited to metrology, the science of measurement, and is
a factor in high-stability crystal oscillators used as time-
bases in frequency counters. Few hobbyists have the
equipment to measure the aging effects which are
typically in the parts per billion range.

What should be of more concern is the temperature curve
of a quartz crystal unit, particularly for portable and mobile
applications. Such is in the parts per million range, a
thousand times greater than typical aging specifications.

All of the major manufacturers of quartz crystal units in the
USA have websites and include specification sheets that
can be filled out by customers for special units, along with
explanations of what is what and limits of specifications for
various types of crystal units. Corning Frequency Control
has a good site with many application notes and papers
about quartz crystals and their characteristics.

http://www.corningfrequency.com

There are many, many factors that drive the cost of a quartz crystal unit. It's a seller's market and few can successfully open a sealed crystal can, tweak a new frequency, reseal it to make it work. Quartz crystal units last much longer if kept intact in their sealed packages.

Important factors for anyone to consider when ordering a quartz crystal unit are -

1. Series or parallel resonance...makes a big difference as to manufacturer's frequency calibration specification. If parallel resonance, the added circuit capacity as stated by maker is the nominal value to be used to hit the stated frequency.
2. Drive level expected...more important for vacuum tube circuits than semiconductors. Manufacturers usually have typical values in common circuits as a guide for customers.
3. If an overtone crystal oscillator is used, compare a maker's application description with the type of circuit you want to use. Improperly used, an overtone oscillator circuit might wind up as just an L-C oscillator with the quartz crystal doing nothing.
4. Ambient operating temperature range expected, "ambient" being the in-board/in-chassis temperature. There will be a drift of frequency over temperature with any quartz crystal unit. Frequency variation over temperature is stated by crystal makers...but curves don't always follow common Handbook figures reprinted for years.
5. Have some way of measuring frequency in your circuit, whether it's an old BC-221 or an ipsy-pipsy $6K box with many digits on the front panel. Without such an instrument all you can say is "it works" or "it doesn't work."
6. Be practical in specifying what you order. 50 PPM (Parts Per Million) manufacturer's stated accuracy is typical and is equal to 0.005 percent (500 Hz at 10 MHz). If a 100 PPM accuracy works in your application and costs less, use it.
7. Many crystal unit manufacturers lay-up stock values based on previous customer demand. Those are quickest to get and usually cost less than custom frequencies. If a stock frequency value will work with some changing of other frequencies in your system, fine...remember that parallel resonance circuits can be trimmed within a few tens of millions part accuracy with a small variable capacitor.
8. Don't expect to get old FT-243 or FT-241 holders shown in 40 to 50 year old amateur literature. The quartz crystal industry has come a long way since the boom of WW2 days...better methods of cutting, grinding, etching, and enclosing crystal units. They usually know how to handle their quartz better than you thought. :-)
9. Don't get off on buzzwords which apply to other technologies in electronics. "Oscillator phase noise" figures won't apply to typical amateur radio applications and most amateurs don't have the equipment to measure that. If you have a

need to toss buzzwords, try to read up on what they mean
and how to measure it first.

From: mcalhoun@ksu.edu
Message-ID: <b4t9un$1sf@unix2.cc.ksu.edu>
Source record: 36942

Yesterday I removed a TV antenna from the tower of a recently-deceased local ham (I bought the tower), and since the antenna is in good-enough shape to revamp into a two-meter beam, I'm just curious: why do some TV antennas have elements which stick out at 90-degree angles from the boom and others have elements which "point forward" at about 45-degree angles? Is this for impedance matching (both kinds are usually "fed" with 300-ohm twin-lead)?

Yes, I've been licensed long enough that I should know everything, but since I don't, I'm asking.

Message-ID: <v74fs937ud3nb7@corp.supernews.com>
Source record: 36943

None of us have been licensed long enough that we know everything.

TV antenna elements are sometimes bent into a V shape to take advantage of the fact that the higher VHF channels are at about three times the frequency of the lower channels. By bending an element, they get a rudimentary V beam and associated gain at the higher channels while the bending has little effect on the lower channels.

I've done the same trick with a 40 meter dipole. A straight 40 meter dipole has a cloverleaf pattern on 15 meters. But by bending each half 30 degrees, the lobes line up on 15 meters to make a bidirectional pattern with a bit of gain. The bending doesn't have much effect on the pattern at 40 meters. Naturally, aligning the lobes, and the associated gain, is useless at best if the lobes don't end up pointing in the directions you want to communicate.

I'm not sure about that. We generally wind a few turns of TV feed-coax
around a ferrite ring in order to fashion a simple but effective
high-pass filter. This has nothing to do with unbalanced currents, but
rather to do with permitting the unfettered delivery of upper-UHF TV
signals whilst blocking the main causes of TV interference: high-power
HF transmissions on the amateur bands between 2Mhz-30Mhz.

I feel I must add, I don't know how much the poster knows about xtals,
but many amateurs don't have the faintest idea about xtals and order
to wrong specifications. Many manufacturers don't understand all
specifications and so you must be careful where you buy xtals.

Remember the old Kenwood xtals were 40pF loading and some rigs even
used series res. xtals with capacitive load

I sent a so-called rubber xtal to the Norwegian Mining to be measured,
and he claimed it was just an ordinary xtal for 15.7MHz, so he could
deliver a similar 10.7MHz xtal, but the problem was that while the
15.7MHz xtal could be pulled +/-20kHz, the 10.7MHz xtal could only be
moved -4kHz, and I had to specify 10.7025khz series - zero load xtal
to get something which worked, but not optimum

A shielded cable would continue to work just fine.
A twinlead cable would definitely have a problem.

Correct me if I am wrong, but I think most articles on building xtal filters do not go into detail about the methodolgy of building a xtal filter involving specifying xtal specs to a manufacturer. The common methodology is pick some cheap xtals, build a circuit, try to get the kind of filter you are after by altering capacitors and input/output impedances. Not the best way to make a filter with specs you are aiming for perhaps, but the methodolgy has it's merits, and there is literature on how to proceed.. But the orther way, of designing a filter with software and proceeding from thereon, proceedings involving xtal specs and manufacturers, there is less information about methodology.

Any xtal manufacturers want to add their 2 cents?

1995. Tips on buying used batteries

Message-ID: <3E7256C4.BDC53A4C@osite.com.br>
Source record: 36948

Guys...

I've found a bargain on gel batteries.
They are about USD 0.85, however they are being sold "as
is".
There are 6 12V batteries of 7Ah capacity, but one of them
have a crack in the bottom.
I gave them a quick glance, but they seem to be stuffed in
the bottom, but these protuberances are scratched.
There is also some solder over the terminals.

The questions:
How can assure myself that they will be useable?
What things do I have to check the batteries before I buy?

I know if they are just discharged, there must be something
around 10 V between the terminals. But I don't know for how
long they were stored.
I have no way to test charge them before I buy.

Hi gang,
It has been a while since I have played with the level of math in this book, but I am having a devil of a time getting some of the formulas to work from this text.

For instance on p 15, formula 1.4-3 should allow one to plot Fig 1.12. Or, in Fig 1.12 there appears to be a rewritten version of formula 1.4-3, but I can't get either to duplicate the graph.

Is there anyone in this group that would be willing to help me see what I'm doing wrong, or, if there are some errors in this book is there an errata sheet available?

Thanks for the help!

Wes Hayward, W7ZOI wrote several articles about crystal ladder filter design which were published in QST and, I believe, QEX. His procedure was to select inexpensive crystals for certain characteristics. At least one article described some simple homebrew test fixtures to do the testing. You'll also find this information, including test fixtures, in Chapter 3 of his new book _Experimental Methods in RF Design_ (ARRL). There's no reason you couldn't order the crystals directly to specification using the criteria in the articles or book, rather than selecting them from a sizeable quantity of cheap crystals, if expense isn't a problem.

Lattice filters are a different critter, and I don't know what's been done in the amateur community with respect to lattice filter design.

Nospamplease is correct. (And with a name like that, he's probably a good fighter, too.)

Winding the coax through the ferrite core presents a high impedance to current on the outside of the cable (common mode current), but has no effect on the signals inside (differential mode). If it suppresses HF signals, it's because the HF signals are traveling along the outside of the line, not the inside. This is a common way for an interfering signal to get into equipment, and the common-mode choke you've created is a common way to cure the problem.

The common-mode choke you've created is a lowpass, not highpass, filter for the current on the outside of the cable. The types of ferrites typically used for this application have significant impedance as low as the HF range.

They might not be a bargain at all, even if they're free -- unless you
have a free and convenient way of disposing of them.

First, hardly any batteries that hams like to call "gel cells" have
gelled electrolyte. It's generally liquid sulphuric acid absorbed into
separator pads. Some have free liquid. A cracked one could leak H2SO4.

Next, if the batteries are discharged to 10 volts at no load after
standing, it's likely you won't be able to charge them again. Allowing a
lead acid cell to discharge too far is fatal.

Finally, if the batteries were pulled from float service, the chances
are very good that their capacity is severely reduced.

The only way you can tell whether they're usable is to fully charge them
(if possible), then discharge at a known rate and measure how long it takes.

Tell you what -- I'll bet you six bucks that the total usable capacity
of the lot of them doesn't exceed 7 Ah.

In hamspeak that is called 'split'. Happens all the time when DXing on 40 phone. Rx low and TX high. However this is normally done with two seperate VFO's so to speak.

Many thanks Roy,
I have thought that they may more of a problem than
anything.
Your post enligthened me a bit more.

Probably used batteries are not wotrh the hassle, isn't it?

Thanks again

Actually, I happened to be looking through the last several months' worth of QST at the library recently....and they had the first several of a series of tutorial articles on the basics of bipolar transistor amplifier circuits (common emitter, emitter follower, etc.) which I thought were quite nicely done.

But in general you are certainly correct about the level of explanations as specific technology gets to be more commonplace.

I'd check the voltage on each. Don't waste your time on any battery
that doesn't show 10-11 volts,
it will have at least one shorted cell and will be unusable.

Those are interesting links to the carbide drills, Tom; I'll be sure to keep them handy.

One thing that I neglected to mention in a previous post is that after the film is developed, it needs to be rinsed off in water (preferrably distilled, but whatever is available). Afterwards, it needs to be placed in the oven again for 10 minutes at 200 deg F. This dries out the film from the developing process, and makes it more durable for etching.

Best Regards,

Sam B.

Message-ID: <b4v9i2$21m49h$1@ID-150848.news.dfncis.de>
Source record: 36961

Thanks for those who have commented on my VFO, IF and xtal enquiries in relation to FR50B and FL50B modifications. I've copied responses to folders to peruse more fully later.

Where the TX is VXO controlled it does dawn on me now that a wideband VXO in the RX might well be sufficient along with a digital frequency counter. Or, where one VFO is used to control TX and RX the obvious solution is to use a xtal oscillator and mixer, sending a different VFO signal to RX from TX, thus allowing the RX IF SSB filter to be different from the TX SSB filter. Thus opening up the way to select RX IF on the basis of cheap readily available xtals, or surplus commercial xtal filters.

I think there is need I think for an article on xtal filter design to cover issues not raised in the articles available at present. I might attend to that.

>to take 600w.

The VHF/UHF DX book (RSGB) has a Breune bridge on page 12-17 that ought to work. Make sure the caps. have a high enough voltage rating to handle 600 watts.
I built a 1200 watt solid state HF amp and used the design Ameritron used on their ALS 600 amp. It combines the rf sense, ALC, and pep watt meter. Seems to work well. You can download the schematic from Ameritron.

Looks nice! :)

Some points:

- "N" is the (2 x pri):(1 x sec) turns ratio of the center tapped push
pull transformer, i.e., not the number of turns.

- The primary and secondary inductance may be calculated after you have
already chosen a xfmr core, and know t.ex. the A_L value for that core.
There are formulas
(http://www.hut.fi/~jwagner/tesla/SSTC/general-sstc-notes-recreading.htm
or http://www.hut.fi/~jwagner/tesla/SSTC/SSTC-Designer.xls (my latter
excel sheet is a bit flawed at some points, tho)) for calculating the
minimum number of pri turns which prevent saturating the core. From
these values you can the continue and estimate the pri & sec
inductances.

- the ESR numbers for the caps - an ESR of 5 ohms sounds a bit drastic,
doesn't it? ;-) Something like 0,005 Ohm or less is more realistic. As
a bonus, the values for C(in) and C(out) capacitances will be positive
then. :-)

Have fun!

And btw, don't concentrate too much maths! :o) (it's all just for
reference, and when you build the circuit, you probably will end up
having to make some extra changes to the pre calculated values in any
case, so there's no reason to loose all hope waist-deep in all that
maths... ;-)

cheers,

- Jan

2012. "Kitchin" books?

I mentioned him, so I suspect it was my post.

Charles Kitchin has not written any books, at least not that I know
of. He has written quite a bit about regen and superregen receivers.

From that post of mine from March 8th:

Someone suggested a one or two transistor receiver. That has
it's merits, since it won't cost you much in parts or effort.
I took it as a hint at a regenerative receiver, which has
the advantage of also showing you something about an oscillator,
since Armstrong basically discovered both at the same time.
In recent years, Charles Kitchin has written quite a bit about
regen receivers (and about superregen receivers too, but they
wouldn't be the best choice for shortwave).

Kitchin, Charles. "A Simple Regen Radio For Beginners", QST
magazine, Sept 2000, pp 61-64.

Kitchin, Charles. "High Performance Regenerative Receiver Design",
QEX magazine, Nov/Dec 1998, pp 24-36.

Kitchin, Charles. "An Ultra Simple W1AW Receiver", QST magazine.
May 1997, pp 34-35.

Kitchin, Charles. "Regenerative Receivers: Past And Present",
Communications Quarterly. Fall 1995, pp 7-26.

A similar article to that last one appeared in Electronics Now
for March 1994, "THe Lost Art of Regeneration".

One of his regen designs appeared in one or more ARRL Handbooks
a few years back (again, don't confuse it with one of his superregen
designs, that has appeared a couple of times in the Handbook).

He's had a few other articles on regen receivers in QST, most recently the September 2000 issue, on page 61.

You might look around the ARRL site, http://www.arrl.org to see if they've put one of his regen articles up there.

If you don't have any of the paper references (or know noone who does), do a websearch with <"charles kitchin" regen> as the searchwords, and you'll find material, either his own or variations on his work.

Just about any ARRL book is going to have some sort of simple receiver. What it will be depends on the era; 35 years ago it would have been a regen, thirty years ago a direct conversion receiver, then more recently a superhet.

Once you have a regen working, you could add a converter ahead of it, and get a basic superheterodyne receiver.

That formula is OK. I was curious, so I typed it into MathCAD and
got the same results as are plotted in the book. Be aware that the
phase term theta (or omega*t) has to be expressed in radians,
even though it's plotted on a scale of degrees in the book.

Hi,

The use of '26' in the denominator of the exponential terms signifies that Vp should be specified in millivolts, i.e. 1, 10, 30, 100, etc., and not as 0.01V, 0.01V, 0.03V, 0.1V. This comes from the reduction of the expression q/kT in 1.4-1.

If you look at 1.4-3, you will see that at 180 degrees the sine term is zero, so the numerator equals one for all values of Vp at that angle and the expression reduces to 1/exp(Vp/26) which is very nearly equal to one for all small (i.e. millivolts) values of Vp.

Cheers - Joe

From: Carl Clawson <carlclawson@earthlink.net>
Message-ID: <sZLca.2516$jA2.234669@newsread2.prod.itd.earthlink.net>
Source record: 36972

Is there a good reference for oscillator circuit characteristics that tells you how to derive crystal load capacitance specs? The usual ham books don't seem to help much.

Many construction articles don't give you a clue, and when they do I usually don't come up with the same number when I analyze the circuit.

Here's the most recent one that stumped me:

The Tuna Tin 2 schematic can be found at http://www.njqrp.org/tuna/tuna_schematic.jpg. The crystal is specified for 30 pF according to the QST article (March 2000). After staring at it for a while and looking up the Pierce oscillator in a few books, I realized that 30 pF is approximately the B-E capacitance of Q1, which is in series with C2 (100 pF) across the crystal.

But there's another path from Q1's base to ground -- through the B-E resistance and C1. This path should be only a few tens of ohms and swamp the B-E capacitance, which is about 750 ohms. So wouldn't the parallel capacitance across the crystal be closer to C2? Or even more, as C4 is in parallel with C2 during at the part of the cycle where Q2 is conducting?

Is it possible that it just isn't that critical (what's a kHz or two between friends) and I'm being overly persnickety? I just have this compulsion to try to understand what I'm doing...I find that it usually helps.

Cheers, and TIA
73, Carl WS7L

A number of crystal makers are now selling programable crystals that
can be user programed like eproms. Infact, they sell a programmer that
you can use to set the frequency yourself. The crystals are cheap,
about $5-10 or so
but the programmer is about $2000. The crystals can be programmed twice
only.
I wonder how these things work.

>>Then, when the customer names a frequency, you edge grind it
>>well away from the conductors to bring it up to frequency and
>>then bang the lid on. All the aging in the conductors
>>and the mounts having already happened and all that double
>>handling cost is saved.

The Drake 4 line receiver and/ or the 2C receiver used that exact method to create the passband tuning. The older drake receivers used tunable 50khz circuits.

Source record: 36981

Hi,

I believe you will find that the crystal is not strictly running at parallel resonance in that circuit and so its shunt capacitance is only marginally involved. Although W1RFI specifies a 30pF rock, I wouldn't think that it matters that much. The collector load is inductive at 7MHz meaning that, together with the 180-ish degree shift through Q1, there is a need for a little more inductance to get 360 around the loop. The crystal should provide this by working on the low side of parallel resonance.

Cheers - Joe

Strictly speaking, parallel resonance is only a crystal parameter. It
is the frequency at which the electrode and package capacitances
resonate with the motional inductance to offer maximum impedance.

Fp = 1 / (2 *pi * sqrt((L1 * C1 * Co) / (C1 + Co)))

where:

L1 = motional inductance

C1 = motional capacitance

Co = shunt capacitance

Oscillators that use the crystal in a "parallel" mode are actually
using the crystal as an inductor. You can look at the crystal +
capacitors as a pi network that delivers both the necessary phase
shift and some impdance change from collector to base.

The "load" capacitance is the value at which the frequency is
specified. Crystals that are specified as "parallel" mode are often
tested with the load capacitance in series with the crystal with the
composite measured as a "series" resonant circuit.

A "parallel" mode crystal specified at a particular load capacitance
can be used in a series mode oscillator (on frequency) by installing
the speciified capacitance in series with the crystal.

In the subject circuit, using the base capacitance is a bit iffy but
probable okay, considering the application.

I have a 40M Rockmite and have had lots of fun with it. There is a lot of activity on the QRP frequency so it is pretty easy to make contacts even with an average antenna.

The PIC processor in the Rockmite provides a keyer but also solves a couple of problems that simple direct conversion xcvrs normally have; it provides a side tone and a 700hz receiver offset. The only problem I had with mine was BCI from a local AM station. There are various simple mods available to solve that problem if you experience it. Have a look at "The Rockmite-Files" at http://www.radioactivehams.com/~n0rc/rm/ . There you will find many pictures of completed Rockmites and lots of mods for it. I apologize if all this is redundant, I haven't received my QST yet so I don't know what is in the article.

Thanks Sam for all the information about using the film. I hope I will be able to get some film and try it out soon.

Concerning the Positive resist spray, I checked this out a little yesterday. I found a spray can of positive resist in the GC Electronics on-line catalog so I called them to find out a little more about it. They told me that the product is currently out of production. They are re-formulating it to try and solve some problem and they don't know when it will be available again. I'm thinking maybe that means never.

interesting, we did some sucessful experiments with bow-horn antennas
for 2m mobile around 1970. The bow-horn antenna proved far better than
the halo, although it is not perfectly omni-directional. Few years
later most turned to vertical, and later to rubber duck and the
activity faded out. Got a German Big-Wheel some years ago, but it is
too large for driving on motorways. Perhaps it is an idea to try the
bowhorn antenna once again for 2m mobile, it is only somewhat larger
than the halo and easy to mount on the roof rack. See

You seem to understand what you write, but I have had some requests
from persons for xtal specs, the last was somebody who had problem to
get the proper xtal for the Yaesu FTR2410A 2m repeater. The
information is so dull, that you must read the text several times,
study the circuit diagram and still you are not really sure, scan a
copy of the manual and hope that the manufacturer has more experience
than you to interprete manuals

I thought that most modern xtals were 25 or 30pF, but still it is lot
of persons who order 32pF load HC50 or HC49 type xtals, I thought this
is a typical load for FT-243 xtals you ordered from JAN crystals 30

years ago. And sometimes you meet yourself in the door because you thought that normal overtone xtals had zero load capacitance, but still somebody mix up with the FT243 paralell resonant mode.

The manufacturers had bad problems when Kenwood appeared on the marked, requiring 40pF load xtals and nobody could buy proper xtals for the 2m rig without buying from the Kenwood dealer.

You seems to know something about xtals. Good. Maybe you should write an artilcle on here that I was thinking I might have to write. I'm away for a week, maybe by then I might come back and see the kind of article I think needs to be written. Well at least that I think *I* need. You must thought know something xtals and filter design methodology as explained by some of the ham writers such as Wes Hayward W7ZOI and JA Hardcastle G3IJR and perhaps others . These methodologies basically involve an empiracle method of acheiving some kind of filter result. Basically, get hold of some cheap xtals, put in some C values, make a measurement, (computer simulation or otherwise) use your findings to help design further. If you want a better filter, then you might seek to mess with a more expensive xtal. You can make an acceptable xtal filter this way, but I was wanting some information that involved a different methodolgy. That methodology basically involved you having a filter spec to reach, use of filter software, (like AADE's) a bit of messing with capacitance and termination impedances perhaps, and at the end coming out with xtal parameters that you want a manufacturer to meet. It's the thing with xtal partameters, how they affect xtal filter design (what does Q do etc) what xtal parameters does a xtal manufacturer really need to know, how, in practice, can the

manufacturer hope to meet your xtal order: it's these things that are nebulous. It is here is where something is very much required to be written IMO.

So, in a sense there are two bits to write, one explaining the old methodologies *in a certain way* (Like: "In these methodolgies we start out only knowing the xtal frequency, (also that they are cheap and freely available), and we are attempting to make the best xtal filter we can with it. We have some control over xtal parameters, (they are...) but our control is somewhat limited because we are stuck with xtal paramemeters the xtal happens to have.....". We can hope to make a better xtal filter by purchasing a more expensive xtal. Acme.com sell pretty good xtals and they are only $1.99...") Notice the kind of way I'm explaining things - what I'm touching upon. The second bit is to deal with the somewhat novel area where the amateur has a filter spec he must reach and *he is willing to buy custom-made xtals.* Now there will be a methodolgy associated with this other approach. And it will involve xtal simulation software, (I'm using AADE) but also the (possibly involved) relationship with xtal specs and xtal manufacturers. It will touch upon xtal parameters and how they affect xtal filter design (For 5 Mhz filters, 5 pole, 8 Khz BW ESR needs to be around 30 Ohms (say) and xtal manufacturers wiil engineer that into the xtal when you specify the xtal parameters in your order). And how in practice we end up with getting a xtal from the manufacturer with the parameters the software indicates. This second part might call for some time-consuming investigation and analysis, and having expereience with xtal manufacturers. Again, it needs to be written in a certain way to illustrate what it is we are embarking upon in practice.

Anybody want to take up the challenge? I'm inexperienced, but I think there is an article to be written. Let's hear something about motional inductance and capacitance. I was hoping even that an employee from a xtal manufacturer could come onboard and write something, explaining things from his/her perspective. I'm hoping that when I return next week, that maybe progress has been made. Report on my desk by next Sunday. Prompt. :c) Rich.

No, but it seems that it would be good to.

Of course a big part of my knowledge gap is the part dealing with xtal manufacturers . Maybe there is no other way but to actually deal with a particular manufacturer, I don't know. I mean can you say to a xtal manufacturer, "Please make a crystal with a motional inductance (L1) of 45mH, motional capactance (C1) of 20fF, and ESR (R1) of 38 Ohms? These issues are what I'm alluding to. In fact, I don't think you can specify a particular value of C1 for a manufacturer to fulfill. Rich.

[...]

Or

Someone with the AADE filter design program (or similar) set out
under the following criteria, to make pre-determied filter with
the following specs (or close to the specs):

1. Ultimate rejection: > 80 dB
2. Ripple: < 2 dB
3. Typical insertion loss: 250 Hz: < 9 dB; 500 Hz: < 7 dB;
SSB/AM: < 6 dB
4. Zin/Zout: 500 ohms

Performance curve:

http://www.qth.com/inrad/graphs/2612_1.gif

Criteria being:

No xtals to measure, just got to get suitable xtals custom-made
from a manufacturer.

Design program at:

http://www.aade.com/filter32/download.htm

I wonder how the methodology would work out.

Anybody with spare time this week to do that? If you do it and
report your findings I'd be much obliged. Rich.

The idea was that maybe huge solar flares could enable radio waves to
travel back and forth
through time. StarTrek used the idea that the suns gravity could
slingshot a space ship through
time travel. Not a shread of fact to support these SF ideas, but it
makes a good story.

Peter is correct in his statement about "the most general way of
generating moduated waveforms ..."

If anyone is interested, you can check out a patent that I hold
that expands upon the Weaver architecture in a way that provides
"feed-forward signal regeneration" to combat multipath fading as
well as incorporating the ability to do not just SSB, a variety of
other waveforms (such as QAM) with the ability to take advantage
of feed-forward signal regeneration to overcome channel impairments.

Search for US Patent # 4,726,069 at http://www.uspto.gov/

If you are going to do a muti-conversion superhet, it is
best to get as much selectivity as soon in the RX chain
as possible, to combat adjacent channel desense,
intermodulation, AGC "pumping" on undesired signals,
and a variety of other reasons.

On the other hand, the trend in industry is to move towards
direct conversion receivers with software-defined (DSP)
"back ends" that do the filtering, demodulation, etc.

Heh, heh... Didn't you know... QST is no longer for "techies"!

Maybe back in the 50's and 60's such an article would fly in QST
but, nowaday's a young "techno-jock" would be lucky just to get
such an article published in QEX.

2058. Very happy with "experiments" circuit results!

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-16 16:17:08 UTC
From: Bert Herald <bert.herald@worldnet.att.net>
Message-ID: <8s1da.11538$S%3.623538@bgtnsc04-news.ops.worldnet.att.net>
Source record: 36861

I just thought I'd share my happiness with my first receiver circuit. I built the one out of the ARRL "experiements" book that I posted about a week or two ago (it's the first circuit in Chapter 1). I had some trouble with the oscillator portion, but I learned a lot about oscillators as a result, and now have a very stable FET-based Hartley. In general, I experimented with many aspects of the circuit and learned quite a bit about coils and refreshed my memory about resonant frequency calcs!

The direct-conversion circuit is based on the NE-602 mixer chip and uses and LM386 for audio amplification. The rest of the parts are pure junkbox (for some people, even those chips might be junkbox!). I got it to work on 40m as it was originally intended, and then redid the coil and capacitor to tune 80m (got tired of hearing all of the AM bc stns squealing into my headset!). It works like a champ on 80m too. I can basically QSY the thing up and down the HF spectrum. I just have to make a new coil and new tap point for the FET and that's it!

I wish I had discovered this part of the hobby sooner. I used to be intimidated by it, and started out building kits instead. But homebrewing your own stuff is so much more fun. I really like the flexibility to make it into whatever you want. I think many more hams would be doing this if they weren't intimidated by feeling it was too hard for them to figure out!

73 and happy building,
Bert

I hear that is the same with RadCom here in UK. :c)

I don't think we are talking about needing a very technical
article actually. Something on the lines of
Wes Hayward's (W7ZOI) or JA Hardcastle's (G3IJR) articles, but
involving a different set of circumstances, ie: no actual xtal
measurements of xtals in hand, main objective of meeting a
particular filter specification, filter software program like
AADE's and a sub objective of procuring appropriate xtals from a
manufacturer.

But there needs to be some mention of C0, C1, R1 & L1 in there,
in some way or other, from some angle or another, even if it's
just to say C1 is never given as a parameter to a xtal
manufacturer. Or whatever. Easy to create a filter schematic with
filter program, and come up with some kind of xtal parameters.
But it's the part dealing with procuring and specifying xtals for
the design which is the stumbling block. Or seems to be.

This thread really ought to be under a different subject heading.

Rich.

I use both Protell and Orcad when I am at work, but when I get
home and have some things to make for my self, I use the best
free CAD program there is, CIRCAD, download a free version
from www.holophas.com you can even get a version that runs
under DOS. CIRCAD is a realy fast working schematic, PCB
and mechanical drawing program, runs very good on small PC's.

Henry,
If you want to know if a used MOV is still functioning as a surge protector, I doubt that there is a good way to do it. A MOV is made up of "sacrificial junctions" with a specified breakdown voltage. Junctions are consumed each time the breakdown voltage is exceeded. Depending on the voltage level and time applied, The MOV could last for years or be consumed in a single event. The MOV continues to protect, and tests OK, as long as there are some junctions left. Test methods that I know of are like starting a car to see if there is gas in the tank; it confirms there is gas but does not tell you how much. I discussed MOV's for equipment surge protection with an engineer at my work; he suggested that they be changed out on a schedule...every year or two.

[snip]

What you ask for is not "easy"...

Indeed it is fairly easy to synthesize LC-ladder filters to meet arbitrary
frequency
domain specifications using modern filter synthesis programs. Such general
purpose
programs have been documented and available for many years. LC-ladder is
one
thing, but crystal-ladder filters represent another whole level of
difficulty. i.e. for
various reasons, crystal filter have never practically been synthesized in
the way
you propose. i.e. start with an attenuation spec then run a rational
polynomial
approximation to the spec and synthesize from the polynomials. There is
simply
no way to guarantee that you will come up with a topology and element values
commensurate with any particular crystal manufacturing technology!

Most existing LC-Ladder filter design programs that I know of do not
automatically produce
crystal-friendly designs. It is possible to "force" some crystal-like
arms and/or branches

by judicious *placement* of loss-peaks, etc... George Szentirmai once wrote a paper
on this technique [1], but even then, although the topology comes out to look like crystal
elements in some of the arms/branches, the element values may or may not be comensurate
with typical, or even atypical, crystal manufacturing technology.

Indeed, for crystal filter synthesis these general programs need to be closely "driven" by a
skilled and knowledgeable practicioner who has intimate knowledge of the crystals at his/her
disposal and the ability to force the intmate details of the approximation and synthesis capabilities
of the program and the requirements of the application to match the available crystal parameters.

cfr:

[1] George Szentirmai, "On the Realization of Crystal Band Pass Filters", IEEE Trans. on
Circuit Theory, Vol. CT-11, pp. 299-301, June, 1964.

For a good "modern" summary of the whole subject. See also Chapter 4 entitled "Crystal and
Ceramic Filters" by George Szentirmai, Cornell University, Ithaca, NY in:

[2] Gabor C. Temes, and Sanjit K. Mitra, "Modern filter theory and design", John Wiley
and Sons, New York, 1973, ISBN: 0-471-85130-2, especially Chapter 4, "Crystal
and Ceramic Filters", pp.121-154.

Personally, I believe that it is much easier for the amateur to take the approach offered by
W7ZOI and G3IJR.

I have a few such LC-ladder programs [older Fortran codes] at my own disposal having
created them for various employers/clients over the years. These programs can be run
by near-novices and usually produce good results. I have often looked at creating a crystal-specific
filter design program of the type you propose, and discovered that it is not easy to do... since
the program "operator" must have too much intimate knowledge of the crystals available and know
enough rational polynomial approximation theory to be able to *force* the program into spitting
out many circuits to be "hand-fitted" to the available crystals.

Unfortunately these days there is not much of a commercial market for new crystal filter designs,

there never was a large market! Certainly not a large enough marke to
justify the work and
expense required to perfect and release such a program.

However, if you want a crystal filter designed, just call...

Hello all.

I'm looking for info for a couple of QRP projects.

Mainly I need a qrp SWR meter. I've seen the tons of info on the internet but alot of it is tailored to milliwatters and the rest of what I've seen is to big and bulky to be semi-trail friendly. I'm looking for simple. around 4 watts max

The second thing is I'm looking for a circut and program that could do keying. I've got a couple of programs that will do audio keying or will do keying with an interface. what I'm looking for is a program that will manually key through a com port (perferablly) like that I could take unhook a straigh key and hook the circut to the key jack.

thanks in advance for any replys.

it is somewhat limited possibilities for what you really can do, the
old IF filter may not be up to modern standards. Had a boatanchor this
age, and the bandwidthes were not to be regarded as they were marked,
and shape factors were very bad.
When it is an old tube radio you probably must replace a lot of the
construction, often such type of radio's had little room for varying
tube carachteristiques. So it might be better to evaluate if it is
really possible to convert it, or sell it as a boatanchor.

Everything depends on your demands, if you don't live in Europe the
40m band may be lot more quite than it is here.

If the receiver is good in other respects I would go for a few xtals
filters bandwidthes after the first mixer, say 1, 2, and 5kHz, and
take the lower selectivity from the lower IF. With my FT-902 I use
DSP-9 to improve selectivity beyond 0.6kHz with the xtal filter.
FT-902 is a triple conversion receiver, but first and third IF is the
same frequency band

Peter

Okay, it seems that I'm asking for something much more difficult
than I can have imagined. There is of course a way or a
methodology of using a xtal filter program which concludes with
the amateur designer obtaining xtals from manufacture. But it's
not simply a matter of amateur designer taking a xtal filter
specification, designer messing about with some parameters, the
program then spewing all the xtal parameters when design
acheived, and said designer saying to xtal manufacturer I want to
order a xtal with a full complement of such and such parameters.
This methodology it seems is not possible. Even with the AADE
program where you can input and choose a selection from C0, C1,
R1 L1, Q, Fp, and Fs. Perhaps in practice only certain xtal
parameters from the design are of any real interest to the
manufacturer. Meaning that you may have L1 C1 etc, but that does
not help with the manufacturer because they are "difficult"
parameters to deal with/order. Things are different though with
the xtal manufacturer who is producing xtal filters, he has
experience that allows him/her to more realistically
obtain/compute all necessary parameters, of the filter and
associated xtals.

One wonders exactly how the amateur designer or the manufacturer
can make use of C0, C1, R1 L1, Q, Fp, and Fs. Maybe there is
some limited methodology asociated with using them. I mean a
methodology involving xtal manufacturer as well as in design of
filter. If the xtal parameters of the design are not orderable,
to the amateur at least, then it's hard to see how knowing them
can be of any use in the end. But, (I think) somehow things can
be made to progress with the manufacturer, in some fashion which
result in obtaining xtals obtained that will do the job. Perhaps
it's just in quoting a limited range of *key* xtal parameters.
Indeed limited parameters are orderable, and maybe they will be
sufficient, or at least that's the only parameters you are going
to get met. Maybe meeting a limited set of *key* parameters are

sufficient.

Normally, I mean it's been typical, (I gather) if there was a deficiency in filter performance, that has been no more than simply supplying a "better" xtal, the amateur having no idea what it's parameters are, only that it is known to give better results, and he will be able to get a better spec filter with the "better" xtal. Probably all the ham knows is that the Q is higher. But it certainly, on test, simulation or otherwise, does the better job. No attempt in this situation to meet an actual filter design spec requirement through choosing or ordering the full gamet of xtal parameters.

Filter design itself, in the mathematical sense may be a complicated business, but the quest is not quite that. It's what is the best methodology you can achieve involving amateurs, cheap xtal filter design program, filter specs, xtal parameters, no measured xtals parameters, and xtal manufacturers. Remember, here the amateur is not making measurements of xtals he's got. He/she has no xtals.

I've been looking at this off and on for a week. So, I could be tallking nonsense. :c)

Getting late here. Must dash. No more postings, or viewings. Away for a week.

Final final.

What I think the sitauation is this.

No xtals made are ever quite like with other in other all in
specs. Esp C1, L1.

Therefore xtal filters with same specs do not contain exact same
xtal parameters.

Therefore xtal filter design must involve actual measurement of
xtal parameters.

Therefore if particular xtals are in hand of manufacturer, and
the particular measured xtal specs that are measured are not
conveyed to designer it's very difficult to design xtal filter
esp if C1 is relied upon as a parameter.

AADE program only maximally suitable where designer measures his
xtal parameters.

Well, a thought.

> hp counters.

According to the display at the Parkes Visitor's Centre,
they had to completely reconstruct the 1969 control room
because the original equipment had all long-since been
scrapped.

The readouts on the downlink receivers aren't quite right,
but are still fairly close to the Apollo CSM downlink
frequency, in round figures, 2.28 GHz.

The only other detail (other than those that "made a good
story", in the words of the Visitor's Centre) was that the
Moon is full in the movie, when it was in fact a waxing
crescent on 20 July 1969 (21 July 1969, local time).

They couldn't actually film in the town of Parkes,
because it has grown a lot in the meantime and doesn't
look anything like it did in 1969. So they used Forbes,
the next down down the road, which still has lots of
old buildings.

It's a fun movie, well worth renting. When I went to
Australia last year Parkes was one of my must-sees
(people thought I was nuts...), and I was most impressed
to see the dish swing around as they mapped pulsars in
the Large Magellanic Cloud.

I'm building a 13.8 volt ps that call for a 18 v 10 amp power transformer. I have found a 28v 25 amp for a song. Would there be any major mods I would have to make to use the larger transformer in this circuit? It uses a lm723 for regulation. It also uses 3 2n3055 pass transistors.

Do I need to give more info?

For a QRP SWR meter, you might take a look at "A Simple and Accurate QRP Directional Wattmeter", in QST, Feb. 1990. It's been reprinted in a number of ARRL publications since.

If you still have a bottle of Tempilac that has gone solid, it's still usable.

Tempilac is not a solution, only a suspension of powder in some kind of liquid. The liquid only helps you to paint a small spot of the solid powder in the right place, in a very thin film. It has to dry out before the test spot is ready for use. Volatile solvents only help it to dry more quickly.

Experiment with various liquids.

Hi,

i'd like to build a frequency controlled filter into an rf preamp.
It's for a direct conversion receiver 0-50MHz, and the LO frequency should
control the input rf bandpass filter center frequency. The filter
pass band bandwidth is fixed.

Are switched capacitor filters any good for this? Or a Tayloe mixer style
setup working as a bandpass filter? Maybe someone has already tried one of
these? (google showed some postings on the topic but not much else than
speculations)
Or are there some "really simple" frequency-controlled RF bandpass filter
alternatives which I just missed?

Thanks!

The conduction voltage of MOV's goes down as they get "used up."
I had one that generated RFI by conducting on the sine wave peak.
Regular replacement is wise given the low cost. Don't get cheap by
getting the tiny ones either.

Also, make sure they are after the switch and not continuously hooked
up to the ac line. No point in having them go bad prematurely.

And finally, don't forget the "metal can" RFI filters. They have
series inductors and parallel capacitors. Transients have higher
frequency components and anything that attenuates them is good.

Hi Folks,
I just bought 100 xtals on 70.7Mhz from Ebay UK, I assume they are either 3rd or 5th overtone, anyway, I've been looking for ladder filter designs, calculations etc.
Mention is made about selecting xtals within 50Hz and similar, low, ESR.
My questions are, should the frequency selection be for parallel or series resonance and how do you measure the ESR of a crystal ?.
thanks Mike W, G8NXD aka M3MSM qthr

2088. filter for electrical RFI noise from converter

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-17 14:53:38 UTC
From: lgagnon@sherrittoil.com
Message-ID: <1d3b4598.0303170653.a36ede3@posting.google.com>
Source record: 36892

Recreational vehicle "converters" are essentially 120-12volt unfiltered, unregulated power supplies having high amp output to power the RV 12 volt circuits and charge the coach batteries (they consist only of a large high amp transformer and diode bridge). I have a 40 amp converter in my 22' Class C motorhome. It has a second 5 amp line to charge the batteries. The converter works ok (as far as converters go) but creates terrible electrical hash RFI noise, very noticeable on short wave frequencies and also on the AM radio band.

My plan is to try to filter out this common-mode noise by installing a quality AC line filter right at the point where the AC line enters the converter and then install some .01uF bypass capacitors on the DC lines where they exit the converter.

Has anyone tried anything similar and if so, what effect did such work have? Or, if anyone has any other suggestions to offer (other than replacing the converter with a proper power supply!) to help eliminate the noise I would really appreciate it.

Is there a reset, set, clear, or other such input that must be in the proper
state before it will count? What about the carry input pin?

I have never used a '290 but have used it's older cousin, the 7490 series.
As I recall the '90 is an asynchronous counter. Depending on your
application you may want to consider one of the synchronous devices such as
the 74LS160series. An asynchronous device may have undesired glitches on
the outputs particularly if you are combining them in other logic gates.

You are interested in the series resonant frequency.

ESR is easy to measure if you have a network analyzer but more difficult in the home lab.

First you need a signal source that has the necessary stability and fine adjustment capability. You need to be able to read frequency to a Hertz. You also need some type of rf voltmeter, power meter, etc. to measure the amplitude of the response.

Imbed the crystal (in series) between a couple of resistive pads that stiffen the source impedance of the generator and provide a load. Drive the crystal with the generator while using the rf indicator to measure the signal through the crystal.

You must be careful to not overdrive the crystal. ESR (and everything else) will change with drive. I would probably shoot for 1 mW at the crystal.

Tune the generator to maximize the response at the meter and note the frequency and amplitude. Leave the generator at this frequency, remove the crystal and substitute low value resistors until you find one that gives the same amplitude as before. The value of the resistor is the ESR.

To do a lot of crystals, you can "calibrate" the meter in units of resistance beforehand by using a range of resistors. This isn't rocket science, as exact values of ESR are usually of secondary importance in both oscillators and filters.

ESR is a measure of both the lead and electrode resistances and the mechanical "friction" of the crystal. As such, its measurement is often more of a screening tool to look for manufacturing defects than it is an important parameter in the end application.

Jim, could you have a look at the datasheet at:
http://www.utm.edu/~leeb/74LS293.pdf

I really don't know anything about this subject, having been involved for the last 40 years with RF rather than digital development. If I need to do anything with the set/reset inputs, the datasheet doesn't give me a clue. I expect that a knowledgeable person (which I am not) would know that!

The 290 is all I have on hand, and no source of much else close at hand. I do have a couple of 74LS74's, if that would help. Can you refer me to a Web digital tutorial that might deal with this subject?

Thanks for your time.

Comparing it briefly to the 7490, I don't see any difference other than
pinouts. (There may be more, but it's not immediately obvious.)

Taking Jim's suggestion about the reset pins, ground them for
just straight decade counting. So ground pins 1 & 3, and pins
12 & 13. You do realize there are two separate sections in there,
a flip-flop that divides by two, and a more complicated section that
divides by 5. You have to jumper the two sections together, one output
to the input of the other, in order to get divide by ten. For that
matter if you don't have that jumper, you won't have output from
the section that isn't being clocked.

How you arrange the two sections may depend on what you are doing.
If you need a square wave out, you'd connect the divide by 2 section
to the output of the divide by 5.

input A ___ /2___QA (pin 9)
(pin 10)

input B ___ /5___QB (pin 5)
(pin 11) QC (pin 4)
QD (pin 8)

Thankyou Wes, I have all thats required for measuring the ESR with
your method, an 9850 dds, VVM etc. Two follow-up queries. When you say
"stiffen up" the source impedance, do you mean a straight 50r/50r
attenuator pad or an pad with impedance step-up eg. 50r/500r, and if
so to what impedance?. Also, what is the usual range of ESR, are we
talking ohms, Kohm, Meg or what ?.

Either you will have to change the regulator to a switching design to
efficiently handle the extra voltage, or add water cooling to the pass
transistors. Even better would be to add a center tap to the 28 volt
winding, to allow a two diode full wave rectifier. But without seeing
the construction of the transformer, I can't say how feasible that
is. You might also just unwind turns from the secondary till you get
the voltage down to the design value. Or you could connect a second
transformer upstream of this one, to reduce the line voltage.

Caveat Emptor.

If you KNOW the source of the batteries, you can sometimes have a bargain on your hands. For example: at work we use Gel Cell batteries for remote telemetry stations. These batteries float on charge most of the time and when the power goes out, they supply 24 volts to the system until the power comes back.

We used to replace these cells based strictly on time in service. We don't do this any more because our battery chargers are being replaced with more intelligent models which monitor charging current at given voltages and raise alarms if the profile is too far off from normal.

You may find some who replace such batteries based on time alone. If you do, you may have something worth using. The key is to know where those batteries have been all their lives and why they were replaced...

Ok gentlemen:
Pin connections are as follows:

1 Grnd
2 n/c
3 Grnd
4 n/c
5 n/c
6 n/c
7 Grnd
8 Q3 output ??????
9 n/c
10 n/c
11 1 mhz TTL input direct from driver
12 Grnd
13 Grnd
14 +4.85 vdc

With this configuration, the only signal I can scope is on pin 11, the input channel

If I try the other diver, with the input on pin 10, I get the same results.

Like the chip is dead.

But I can get it ti switch states if I apply +vcc or grnd via a 10k resistor to pins 1/3, 12/13 if I lift them from ground first.

> transistors.

Well, yes, things will be a bit different. _IF_ the 28V transformer
has a center-tap, there's some hope of making it work efficiently, but
if not, you will start out with too high a voltage to make it
practical to regulate down with a linear pass system. For example,
assuming a capacitor-input filter in both cases, the 18V transformer
would try to charge the capacitor to a peak of about 24 volts. It
won't make it quite that high under load, and there will be ripple.
The average might be, say, 21 volts or so. If you are wanting to draw
10 amps from the output, and you're dropping to 13.8V, that's 7.2V*10A
= 72 watts dissipation. That's quite a bit. Think "75-W light bulb".
But the 28V transformer will deliver nominally 38V peak to the
capacitor, and since it's a higher-current transformer, it may
actually deliver a bit more, assuming the voltage rating is at full
load. So assuming a similar ripple, the average voltage at the filter
cap might be 36V. Now you're dropping 22.2V, still at 10A, so you
have 222W power dissipation in the pass elements, just to get 138W
output. Also, the peak voltage (which might be up close to 45V with
no load and high line) might damage parts unless you're careful about
the design.

If the 28V transformer has a center-tap, you could reasonably make a
more efficient supply, using a full-wave center-tapped configuration.
Then you might have 19V peak at the cap, and with a 6,000uF cap, you'd
have about 3V p-p ripple. That would give a minimum voltage at
negative-going peaks of the ripple of 16V, leaving plenty of headroom
for the pass elements. Even if the peak was only 17.5V, you could
have enough headroom, IF you're careful about the pass design. With
this scenario, about 17.5V average dropped to 13.8V, the dissipation
is only 37W at 10A, which is a respectable efficiency. Just beware of
low line inputs! Also, the optimum design will probably be a bit
different from what you're starting with.

Cheers,
Tom

For some **&(@*^& reason, the thing has begun to work properly. Now it is running at 10 mhz & I am watching the 10 & 1 mhz outputs on the scope. I have tested it on the breadboard to 17mhz, so that should be a good enough margin. Bypassing Vcc to ground made no difference.

It is indeed necessary to ground the master set & reset pins 1&3, 12&13. The division quits if they are floating.

I have no idea why the original failure. Are there Leprechauns (sp) about?

Many thanks for the steer in the right direction.

Hi,

There is an article in the Jan/Feb 2002 issue of QEX by Jack Hardcastle, G3JIR that sets out the procedure. His method also enables you to evaluate the series/shunt capacitances and by extension the Q. The draughtsman inadvertently added a crystal to the series network but that will be obvious when you look at it.

I used his method to check out some cheap computer crystals for use in a narrow spectrum analyser filter. If you have any difficulty finding a copy of the article, please email me.

Cheers - Joe

How are you wiring it up, on a breadboard? If so, perhaps one
wire was not making proper contact, something I've noticed from
time to time when using those white breadboards.

I agree that the book is an excellent, indispensible one -- we're lucky to have it at all. But I don't think I'm "whining" when I express my disenchantment with a $50 trade paperback whose schematics appear to have been drafted with a $25 shareware CAD program.

Contrary to being an ARRL-basher, I'd point out that ARRL publications have set a high standard for quality electronic draftsmanship for at least the past fifty years. It's a shame that they chose the occasion of Wes Hayward's long-awaited release to drop their production-quality standards. I expect more precisely *because* this is an ARRL publication.

BAD CONCLUSION! Better would have been "It depends...."

I have a "deal" with the electronics technician in our local hospital:
he changes lots of batteries in lots of equipment (portable X-ray machine,
lap-top computers, etc.), and, instead of disposing of them however he
formerly did, he gives all of them to me. I test them, pass those that
are really "dead" on to the County recycle people, and then either use
the rest myself or make them available to other hams in the County.

For example, of each TEN X-ray batteries (10 x 12 = 120 volts), usually
only two or three are bad, which means seven or eight are good! And
they are 16 amp-hour batteries -- large enough to be quite useful.

Just last week someone gave me a UPS with a totally-dead internal battery;
I replaced it with a hospital battery having the IDENTICAL form, and all
I had to cobble was a slightly-different connector! The computer I am
using at this instant is now powered by that UPS!

Your mileage may vary for used batteries from a ham-fest.

This is the last of a few Tek 49x-series analyzers I've gone through and repaired/calibrated. It has a very fresh CRT, a spot-on calibration job (at least as far as I can tell without NIST-certified standards), and a new coat of paint on the cabinet, thanks to the OEM-quality Tek Blue paint formulated by Stan Griffiths W7NI.

Parenthetically, this was the first time I'd used Stan's paint on anything, and I highly recommend it to any Tek scope owners who want to clean up their gear. I was impressed with the color match and finish quality; the photos in the auction don't really do it justice. Drop Stan a line at w7ni (at) easystreet.com if interested.

Operating/service manuals and the 18-40 GHz waveguide mixers are included.

From what I've seen, police radar detectors seem to be respond to X-band
signals around 60 MHz either side of 10.525 GHz. You might set one
Gunnplexer to the middle of that band, and then use the IF to tune
another one relative to it. Rotate the tuning screw clockwise to lower
the output frequency.

2118. Re: Crystal specifications for oscillators

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-18 05:51:18 UTC
From: Carl Clawson <carlclawson@earthlink.net>
Message-ID: <qtyda.6000$jA2.623496@newsread2.prod.itd.earthlink.net>
Source record: 36822

Anyhow, back to my original topic,
news:sZLca.2516$jA2.234669@newsread2.prod.itd.earthlink.net...

I resolved most of my confusion. Some of it was a simple error in computing Q1's bias point. Another error was using the little high-frequency transistor model that you find in chapter 1 of Solid State Design. It shows a current gain of fT/f and an input resistance of 26 mV * (fT/f) / IE. Well, if you instead use the hybrid-pi model and approximate it well above fT/beta, you get these formulas except for a phase shift of 90 degrees. So the input "resistance" in the picture is really the impedance of the base-emitter capacitance itself, not an ohmic resistance shunting it.

Correcting all that, I come up with roughly 50 pF for the BE capacitance. With the 100 pF of C2 in series, you're close to 30 pF. (It will be device-dependent due to fT variations.) Then there's a catch: the crystal in the Pierce oscillator is series resonant, so the analysis is a bit different than I had thought. But it turns out that you want the series capacitance combination to match the load capacitance of the crystal, so 30 pF is about right.

Thanks again to the folks who pointed me to some references here. I'll throw out a couple more that I found helpful.

We have done some work on the Tayloe mixer - it appears to act as quite a good filter at carrier frequency. You can mix the signal back up to the carrier or an IF frequency with a second mixer in reverse. I am not sure how it goes at harmonics - presumably it will have a spurious response as the LO drive is 4 digital signals. I am designing just such a receiver at present Rod Green (VK6KRG) has tried this concept on 7 MHz with a Tayloe mixer frontend and an IF at 455 KHz. You get SSB rejection of about 40 dB without any special balancing of the 4 signal paths. The beauty of this setup is that there are no phase shift networks in the audio path. He claims MDS for 20dB SINAD was -110dBm and mixer 1 dB compression was about 0 dBm. (FST3125 mixer with no RF amp) It has good adjacent signal performance due to the inherent attenuation of off channel signals - in short the ideal reciever topology!
Has anyone else got experience with this setup?

FOR SALE - Filament Transformers

Ready to build that BIG final amp?
Suitable for linear amplifier, repeater amplifier project etc.
Ideal for 3CX3000 Amplifier and other 7.5V tubes such as 8161,
3CX2500A3, 3CX2500D3, 3CX1000A3, Pair of 3CX1200A7 etc.

Thordarson 21F26 Transformer.
Top Quality. 115/230V AC Primary 50/60 Hz
to 7.5 Volts C.T. at 51 Amps.

Dimensions: 5" wide X 4.5" Deep X 4" tall

Will sell for $110.00 plus shipping

E-mail me to arrange purchase

http://come.to/AF4K/

Not by my definition. That may be what Microchip states in places in
the reference you cite below but their own figure 6 (and verbage in
"Specifying a Crystal") proves otherwise. The crystal is operated
above series resonance and below anti-resonance and is for all intents
an inductor. He's a test. If you can't replace the crystal with a
resistor equal to ESR and have the circuit still oscillate, it's *not*
series resonant.

In other words, the crystal is required to supply some phase shift to
satisfy Barkhausen, and it isn't zero degrees.

Thanks!
It's a good filter on the audio freq side, but I'd need the quadrature
outputs. And input RF amplification, to use my existing dual AD831 I/Q
mixer board (dead-weak reception with no preamp).

My "idea" is:

```
RF ___
/ \
------/ \-------------------
^
| filter f_c == LO I or Q
| bandwidth = 200 kHz, maybe
|
+-> rf preamp --> 2 x AD831 mixer --> I & Q AF
^
|
LO I and Q
```

About the Tayloe mixer:

> You can mix the signal back up to the
> carrier or an IF frequency with a second mixer in reverse. I am not sure how
> it goes at harmonics - presumably it will have a spurious response as the LO
> drive is 4 digital signals.

Probably lot's of digital clock feedthrough - switch gate capacitances -
into the output. But these seem to be below -30dB
(http://www.hut.fi/~jwagner/dc-rx/N-path-SC_bandpass.pdf)

Maybe it works. OTOH, odd, two mixers for down and then up conversion, and
then a RF preamp, and after that, quadrature mixer.
Highly unconventional... ;-) Well, if I can't invent anything ingenious
of my own, that'll have to do. Though I've some doubts about the
performance of such a setup.

But the Tayloe mixer (or N-path filter) gave an idea - modify it into a
band reject filter, so all out-of receiving band signals are terminated
on the output side of the mixer. And amplify the remaining in-band signal
from the input side of the mixer. I'll give that one a try.

Sounds very good. 8-)

It didn't use the 455kHz IF for a second upconversion, though? ;)

Ok - any thoughts on how to use the AD9854 for this? Are four ultrafast
analog comparators sufficient? (square up the I, Q, inverted I and Q?)
If yes - have you used fast comps in your setup? NE521, other?

many thanks!!

For an idea of the ranges of all crystal parameters, try
prowling the document pages at the Corning Frequency
Control website. www.corningfrequency.com

Try other quartz crystal unit makers' sites for similar data.

Quartz crystal unit manufacturers cannot supply exact values
of the equivalent electrical circuit other than frequency. The
values of things like motional capacitance is a consequence
of many interrelated factors. Manufacturers wind up with the
equivalent circuit "component" values within certain ranges.

Applying those ranges to oscillator circuits requires mainly
recognizing a very low impedance across the unit (series
resonance) or a very high impedance (parallel resonance)
and picking the right circuit to accommodate that. Parallel
resonance applications have a specified external circuit
capacitance for the frequency desired by the customer.

Parallel resonance of a quartz crystal unit is dependent both
on equivalent quartz unit parallel capacity and that of its
holder AND the external circuit capacity. That allows
addition of a parallel trimmer capacitor to "set" the desired
frequency in-circuit. That settability is only a few tens of
parts per million.

Series resonance is almost entirely a function of the quartz unit by itself. Addition of a series capacitance in the circuit does allow some trimming but that trimmability is of lesser range than with the parallel resonance circuit.

If this is the RTS software, the interconnect cable is not as simple
as it seems - there is level changing/logic circuitry inside the DB9
connector housing...at least this is the way it is set up for my IC-2000.

There was a recent article in QST about how to do that, and a recent
thread here as well.

If you do lots of electronics tinkering, you might want to have
multiple power supplies in one package. Might have to add a little
filtering.

2140. practise code osc question

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-19 00:10:06 UTC
From: John Bartley <jcb@igs.net>
Message-ID: <3e77b30a_2@corp-news.newsgroups.com>
Source record: 36842

Hi all

I'm about to try building an code prectise oscillator. The front end (simplified) of my design is here: http://www.ott.igs.net/~jcb/misc/osc/Osc.tif The idea is to have a choice of three tones so that it doesn't get too monotonous. My question is; I understand the concept of the voltage divider in a colpitts osc, but can't find any books which discuss the impact of a much larger cap across the inductor and how that affects the value of the voltage divider caps. My thinking is that the tank circuit, which is composed of the two trimmers making the voltage divider parallelled (sp?) with the switched in/out caps tanked with the inductor, will form a tank circuit unto themselves and the trimmers will work as dividers regardless because they are the only caps between grid/plate and grid/cathode So how wrong am I?

cheers

Keep in mind that these are usually (always?) switching supplies. You might
want to consider ways to synchronize the switching with an external source and
then tune it to move any birdies out of the band of interest.

2143. Source of CHEAP amphenol 8 pin connectors found!

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-19 01:14:13 UTC
From: Paulo Marcondes <pepm@osite.com.br>
Message-ID: <3E77C465.FAD1FCD6@osite.com.br>
Source record: 36846

I found a source of amphenol 97 series connectors in Brazil,
they sell for USD 1.16 each

97-3106A-20-7S (socket, 8 contacts), without cable clamps,
with
plastic cap
97-3102A-20-7P (chassis mount, 8 contacts), with plastic cap

Almost all in original packaging, mint or near-mint
condition, seems never used.

I've seen some cable clamps, but I was not able to determine
their part numbers.

I want to know if you have any interest on these items.
I can buy myself then ship via UPS/FEDEX or express mail.

I bought myself a dozen, since this is a very hard-to-find
item here.

I did not read the first message from Woody completely when I first
replied. Did not realize he was trying for a direct connect from the
serial port. You are correct Don, he needs to have a RS-232 to TTL
level convertor between the serial port and the radio. Icom uses just
a couple of transistors. There are many designs on the " net " too for
such a device including some using a MAX-232 chip.

Thanks All,

Subsequent research also indicated the same... Level
conversion/buffers. No trouble to build, just hope I didn't toast the
v8000 I/O. True RS-232 is pretty robust (the PC com ports are fine),
but don't know 'bout the radio. At least it otherwise seems to work
well. ...Was a bit naive when the interface was referred to as RS-232
at some point when I was checking out the radio capabilities.

Another characteristic in the data I found is a single bi-directional
line rather than (2) Rx/Tx lines. The ring is typically shown to be
active, not the tip. On power-up, however, the 'scope did show what
appeared to be a short data burst(?) of just a few bits from the tip
line. The ring went to TTL Hi (+5) and remained static. Any
Comments???

Tnx agn,
Woody

A while back there were a series of articles in the QRP publications about converting these supplies. They were referred to as "St. Louis Switcher" supplies. Unfortunately, when I google on anything like that, I come up with hundreds of Missouri power supply manufacturers, but I know there's some stuff on the web.

You might try grazing the NJQRP and QRPARCI sites.

They aren't always the best choice. Their high current is in the
5V line, and the +12V line has a lesser current. They'll require
a load to operate, so they aren't particularly useful unless you
do need the current. They are noisy in terms of RF, and the outputs
aren't always that clean.

I was accumulating them too. I kept finding them, in remains of
computers waiting for the garbage pickup, and sometimes just lying
on the sidewalk by themselves. Last year I decided I had way more
than I could ever use, even if I did have a use for them.

So I stripped them down. You get some high voltage capacitors,
if you need those. A nice high current bridge rectifier that
could be used in some other supply. Some low voltage filter capacitors,
that aren't so useful in linear supplies since they have relatively
low capacitance (around 1000uF). Some high current diodes on the secondary
side. Some power transistors, sometimes mosfets. Various other
components that might be useful in some specific cases.

But there was also the case. Many of the supplies I stripped was
a nice convenient size. Ironically, I built up three linear power
supplies in three of the cases, using transformers I'd pulled out
of other scrap equipment. I covered the back, where the fan was,
with a piece of unetched circuit board (easy to work with, and
I have more of it than scrap sheet metal). I kept the switch
and female power jack in place.

But the case is of a nice size that I can think of all kinds
of things I could built in them. Cases can often be more costly
than the parts you put inside, and such an available supply means
that one can build without much consideration to cost.

You could try to connect three identical (+5 V) power supplies in series to get +15 V and use a linear regulator (series pass transistor) to drop the voltage to 13.8 V, this series pass transistor also reduces the noise on the power rail. The base circuitry of the series pass transistor could be driven by the +12 V of the topmost power supply, thus 1.2 V Vce voltage drop across the series pass transistor could be realistic (still below saturation), even if the Vbe drop is 1.5 V or more.

However, the problem with many (most/all ?) PC power supplies is that the 0 V DC line is connected to the enclosure, thus this connection must be removed, so that all the enclosures can be connected in parallel to the safety ground on the primary side.

Source record: 36755

I use one to power my homebrew station. See photograph:
http://www.hanssummers.com/radio/g0upl/qsl/index.htm, the ex-Compaq PSU is re-cased in an aluminium box on the left. It has appropriate connectors on the front panel for general workbench use, and also a socket on the back which connects to the radio.

In use I haven't had any noise problem. I tried my old linear PSU http://www.hanssummers.com/electronics/equipment/psu/index.htm, which sounded identical except for significant 50Hz hum which is absent with the switch-mode supply.

They do require a minimum current drain. It seems to work Ok placing a high wattage low-value resistor across the 5V and GND (i.e. you don't need to take minimum current from all voltage outputs). I uses 10-ohm 10-watt.

I am also using PC power supplies for this large LED display project I'm making for my employer http://www.hanssummers.com/electronics/equipment/riskometer/index.htm. The peak current consumption of the 17,600 LED's is 5V @ 100A, so they are connected in 4 banks, each supplied by a standard 300W computer PSU. There are also LM75 temperature monitors with automatic relay cut-off in case of problems. These PSU's are also Ok with 10-ohm, 10-watt resistors. Without the resistors the PSU just cuts out.

Woody,

Yes the cloning connection is a single line. The cpu is generally feed
with two transistors, one for inbound data and one for outbound data.
Both are attached to the same data line. I don't remember the actual
data level on the radio when you power it up. I am not aware of any
changes in the cloning system over the various model changes.
Any Icom mobile with cloning should act the same as the V8000.

Help
I need to find some GR type 774 connectors for a recently found 916-A RF bridge, I don't think I've ever seen any here in the UK. I'd appreciate any help or pointers including dimensions of the connector in case I have to make some, I'm thinking of maybe turning down the thread on an SO239 barrel (i.e. socket to socket) as a short term measure.
I'd also welcome any comments on the 916-A bridge from anyone with experience of using one, the construction looks amazing. What would you think of running it with a modulated noise source generator?
I didn't get the two "unknown" connecting cables (long and short), the manual tells me they have 250ohm resistors in series - do you see any problems with making my own? I guess I should try it and see if I can balance the bridge.
Thanks
John

Are you sure this isn't an 874? I've never heard of a 774, but there
are things in this world that I've not heard of ;-)

The 874 is a hermaphroditic connector. Any one will mate with any
other. There is no concept of male and female. The barrel is divided
into four segments, two are pushed in, and two pushed out, so if you
rotate the connector 90 degrees, you get a mating orientation. The
center conductor is simiilarly arranged.

You can find these all the time on ebay. They're not expensive. The
connector is rated for operation to 7.4 GHz (hence the name). The
simplest thing is to get adapters to BNC or such.

Search for 874 in Business & Industrial > Test, Measurement Equipment

There's an attenuator on ebay at the moment which includes two
874-to-BNC adapters, two 875-to-PL259 adapters and a 50-ohm terminator
with an 874 connector. The attenuator itself might be of interest.
And it's in the UK. See

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=3013904397&category=1502

I'll try to dig up some info on the 916 bridge.

Leigh
Thanks for the reply, the connector is not the hemaphrodite type and the manual details it as a 774 series, it is from the 1940s so I guess it's an earlier type. The panel connector has a recessed hole about 1/2" diameter with a sunken centre pin, there is a lip raised above the panel around the hole which may mate with an outer sleeve on the cable jack - shouldn't be too hard to fabricate something.
Thanks
John

Have you opened up theunit to see how much space there is? If all else
fails, you might consider replacing the connector with an N type, or such.

Hi John,

Modulated noise source? Well, anyway, noise used as a source will
require a VERY large amplifier to work to any degree of precision.
The problem here is that noise sources suffer both from evenness of
output level across frequency for one, and low output level at any one
frequency for another.

These class of bridges will exhibit extremely deep nulls (100dB
easily) that in turn require at least drive levels of 0dBm to allow
you to find the bottom of the balance at 1ï¿½V (using a communications
receiver as the detector). 0dBM doesn't sound like much from a
source, until you spread it across the spectrum instead of offering it
to one frequency.

My noise source is a Photomultiplier tube that is weakly illuminated
by a constant illumination and offers a very wideband and flat
operation out to a hundred MHz, but needs amplification (which then
upsets this even power distribution) to do a low precision measurement
(not very satisfying). Instead, I use an HP 608F VHF Signal Generator
(actually starts at 10MHz) which has a rock solid stable output (very
important that 100dB deep nulls don't drift).

As far as connectors go, the only one that counts is the "unknown"
terminal. The source and detector can easily be converted (easily in
the sense of just go ahead and do it without concern) to any connector
technology you wish. For that matter, the "unknown" connector is (for
my bridge) a simple stud. I converted that to accept a connector (a
flying design where the center pin screws into the stud, and the shell
is supported by a sheet of copper tied off to the nearby ground
connection).

A picture of this is available on request.

Most of these so-called "modifications" simply consist of hanging a load resistor across the 5V output and taking whatever comes from the 12V line, which is *not* regulated against current demand.

If you're using this with an SSB transceiver that really needs 13.8V at 20A to develop full undistorted output on speech peaks, you're going to be disappointed - and splattering.

The Australian article looks far better:
http://www.qsl.net/vk4ba/projects/index.html

It shows how to make the "12V" output adjustable to 13.8V, and how to move the existing voltage regulation and over/under-voltage protection features from the 5V output to the 13.8V line. You then have a fully regulated and protected 13.8V high-current supply.

It's more complicated than the "entry level" approach, but the extra effort looks well worthwhile.

That's not such a good idea. Most radios have a fixed cw offset of 700 Hz. Learn a different one and you will transmit off frequency. If you have, or plan to buy or build a rig with a different or adjustable offset, then you should play around with the one that works best for you and learn with it. But be aware that the code test is at 700 Hz.

In the end though, a practice oscilator is really only needed until you can pass the 5wpm test. Much better practice is to copy off the air, especialy while "talking" to someone.

Aahhh - thank you. That answers a question that I wouldn't have known to
ask.
The idea then, if I have it correct, is to be familiar with that most
common tone so as to be comfortable tuning to it, and be able to
recognise it easily.
That would also cause less stress at exam time.

thank you again

cheers

Hi Pete,

Useful, I am sure, but with only 1mW across 1.3GHz, this works out to
roughly -60dBm for any frequency that is received with a 10kHz BW.
This is being quite generous, but for the purposes of driving a good
bridge, this excitation (albeit well over S9) is just not enough.

I'm getting ready to do some diddling (ahem, that's "heuristic engineering" if you get paid for it) with direct (or zero-IF) conversion receivers. Before I get started, something is bugging me and I can't start experimenting on something that is doomed to failure from the getgo.

Let's presume a regular old double-sideband full carrier VHF AM signal, crystal controlled. Let's presume the receiver also has a crystal controlled LO.

Given the tolerance on crystals, say a really good 0.002% over temperature, that means that the transmitter could drift somewhere around 3 kHz on 2 meters and the LO could do the same. Perhaps they would zero beat each other, but the odds are not good. Mathematically, the odds are best for a heterodyne somewhere between 1 and 2 kHz., a loud audible tone.

How do you get rid of the heterodyne, given that it will change over time, temperature, and tuning from one end of the band to the other?

Are you asking about how to maintain good frequency control, or are
you asking how to build a costas loop?

Is the goal to build a direct conversion receiver, or to build
something simple?

I don't think direct conversion is a good way to detect AM in a case like this, unless you can lock the oscillator onto the carrier. You might take a look into synchronous AM detection methods in which the "LO" signal applied to the mixer isn't from an oscillator, but is actually derived from the carrier, insuring perfect zero beat. I have a little Sony receiver that uses this method -- I believe it's sometimes described as "synchrodyne" detection. Hopefully someone with direct experience with AM detection can provide more detail.

Huh? Why use an LO at all? Use a germanium diode and "detect" the RF
directly, like the old crystal radio sets, then feed the low level audio
to an amp. Selectivity won't be great, but I don't think that's the
forte of DC receivers either!

There was a circuit in QST some time ago on a synchronous detector.
This is an AM detector designed to work on a reduced carier AM signal
(which some of the sw broadcasters thought of using). It uses a local bfo
phase locked to the (reduced) carier.

The Antennex article says that if one wants to get more
current, it has to parallell (sp?) some supplies, protecting
them with diodes.

Does anyone has any ideas on how to do this?
I am clueless about electronics, but willing to learn.

The australian way, posted below in the thread seems an
interesting way to follow.
But, if I wanted a 40A capable power supply, I would have to
place two of these in parallell.

> and learn with it. But be aware that the code test is at 700 Hz.

Well all four of my Kenwoods (all different models and vintages) have an
offset of 800 Hz.

Even ff your radio has a fixed offset, one can use the RIT control to listen
at a tone they prefer that is easiest for them to work with and yet still
transmit on the correct frequency.

>
> Scott
> N0EDV
>
Actually, no.

In a direct conversion receiver, whatever is in the audio chain
determines the selectivity.

The mixer is just translating everything it sees down to DC and up.
So if the oscillator is tuned to 10MHz, a 10MHz signal at the input
of the mixer translates down to 0Hz (ie zero-beat) a 10.001MHz
signal translates down to 1KHz, and a 10.020MHz signal translates
down to 20KHz, almost above hearing range. Since the audio
stages after the mixer are likely/hopefully limited to the audio
range, it slices off the signals that translate to higher than audio
frequencies. And hopefully there is an audio filter of some sort
between the mixer and audio chain, that will limit the signals
that come out of the audio amplifier. If you have a low pass filter
that cuts off at 5KHz, you won't hear any signals that are higher
in frequency from the local oscillator. Also, except if two
stations are on the same frequency, they will translate to different
audio frequencies, so you can discriminate that way.

Note that no selectivity is needed before the mixer. Of course,
in most practical designs there is some sort of filtering there,
not for ultimate selectivity but to protect the mixer, which
will be less than ideal.

The case of some sort of filter followed by a diode detector is different.
If you don't have a good filter ahead of that detector, it will not
be able to differentiate between one station and the next. Each separate
station within the passband of the front-end filter will be converted
to audio, and there is nothing for you to differentiate between a
station at 1020KHz and a station at 1030KHz. Any audio filtering after the
detector will merely limit frequency response, not limit the passband of
the receiver.

The problem with a direct conversion receiver, as describe so far,
is that it can't tell the difference between a signal below zero-beat
and one above it. A signal at 9.999MHz and a signal at 10.001MHz will

both translate down to 1KHz. For that, you do need selectivity before
the mixer. Or, as usually the case in DC receivers where they don't want
this problem, two mixers and phasing networks are used, to select which
of the two images is desired.

The Radio and Electronic Engineer was the Journal of the Institution of Radio and Electronic Engineers in the UK. It merged with the Institution of Electrical Engineers in ca. 1989.

The paper referred to from March 1973 was:

1. S.R. Al-Araji & Prof. W. Gosling, 'Direct conversion s.s.b. receivers', Radio and Electronic Engineer, Vol. 43, No. 3, pp 209-215, March 1973

This paper references a second one by the same authors which was published four months later.

2. S.R. Al-Araji & Prof. W. Gosling, 'A direct conversion v.h.f receiver', Radio and Electronic Engineer, Vol. 43, No. 7, pp 442-446, July 1973

In the first paper, they discuss the 'Weaver' method as follows:
"... This receiver is essentially equivalent to a class of band-pass filter proposed by Barber [4], and the circuit was first suggested for s.s.b. generation by Hall [5]. Weaver [6] drew attention to its possible use as a receiver, and for this reason it is known as Weaver's 'third method' of s.s.b. reception."

In the July 1973 paper (which was possibly written first) the design is refereed to as the Barber receiver.

[4] Barber, N.F., 'A narrow band-pass filter using modulation', Wireless Engineer, Vol 24, pp 132-134, March 1947

[5] Hall J.R., 'A phase rotation single sideband generating system', RCA Review, Vol 16, pp 43-51, March 1955

[6] Weaver, D.K. Jr., 'A third method of generation and detection of single sideband signals', Proc I.R.E. Vol 44, pp 1703-1705, Dec 1956

Some comments:
i) The idea of the filter described by Barber was to mix the signal to be filtered to baseband, filter it and then mix it back to the original frequency. It has a two channel band pass filter. In the first channel the input is multiplied by sin (wt) put through a low pass filter, and then multiplied by cos (wt). In the second channel the input signal is multiplied by cos (wt) put through a low paas filter, and then multiplied by - sin (wt). The output from the filter is the sum of the two channels.

ii) I have looked at the 1955 paper by Hall and do not understand how it fits with the Barber / Weaver configuration. The circuit uses four modulators, but appears to require a wideband audio phase-shift network.

There is also the 'fourth' method of SSB generation and detection, using polyphase networks. You can find an extensive bibliography, and copies of papers at Mike Gingell's (now KN4BS, I think) web page at http://users.vnet.net/gingell/polyphas/polyphas.html

Quite true, but the CMOS switch type mixer at the heart
of the Tayloe Detector (/Mixer) seems to be the best for
the lowest intermodulation products.

On the minus side for the Tayloe fans is there must be much
more attention paid to sub-microvolt audio range noise at
that mixer's output and the first of the audio amplifier stages.

The four SPST CMOS switches in the one package for a Tayloe
input stage will interface directly to the Gingell polyphase
network and, presto, an AM SSB receiver. No problem on
selecting upper or lower sideband...switching is done at audio
at the output of the polyphase network. One "mixer"...but needing
4 times the LO frequency required to get the four quadrature-phase
RF LO signals.

Hans Summers did good on his ham rig using the Tayloe and
a Gingell polyphase network, network values modified later in
an article available for downloading on his website.

Thanks, Wes, you are right.

When I read that Microchip note it seemed to make sense, but I must have made a mistake mentally adding up the phase shifts. For me, there's no substitute for sitting down with pencil and paper and grinding out the details. When I do that it works out that you need the crystal to be inductive -- and that's what a parallel resonant crystal looks like.

I think I know what you mean; I had been using it with a Spectrum Analyzer,
to characterize filters. It sounds like it would need extra amplification
in order to meet the needs of a bridge.

>

Yes there is clock feedthrough
In the first mixer this is irrelevant is the output is audio.
The second is at 455 KHz output (4 paths in - 1 out) There will be clock feedthrough here but the signal is product detected in the third stage back down to audio using the same clock and the feed through ends up as DC.
The signal is translated from signal to audio to IF and you can filter it there. There is an SSB image down about 40 dB on the prototype The image is the inverse of the wanted signal ie - USB -> LSB and vice versa
In practice the receiver seems sensirtive and birdies dont seem to be a problem.

This should work except that the feedthrough will give you a carrier at LO freq. The impedance of the mixer seems to fall off rapidly either side of the LO freq. If you used the same LO for a direct conversion scheme I guess this wouldnt matter

I had the theory *slightly* wrong here. The circuit effectively translates the wanted signal spectrum to IF via audio.
You then product detect the audio after appropriate filtering etc. The beauty is you can use an IF filter without IF image issues.

> It didn't use the 455kHz IF for a second upconversion, though? ;)

Hi,

and thanks for the clarifications! I'll be off to reading & building.

Just a quick last comment:

> > Ok - any thoughts on how to use the AD9854 for this? Are four ultrafast
> > analog comparators sufficient? (square up the I, Q, inverted I and Q?)
> > If yes - have you used fast comps in your setup? NE521, other?
> >
> The AD9854 does not seem to have any immediate application unless you want
> to use a single output at 4X LO and divide it down in a Johnson Ring counter
> to get 4 phases

Actually, if you draw the DDS I & Q output signals on paper, then you'll
notice it counts "10 11 01 00 ..." - a 2-bit Gray code counter.

So there's no need for 4 x LO or 2 x XOR pulse doublers, and no extra
counter chip required either. Yes, the multiplexer outputs won't be
conveniently ordered in a linear 0-90-180-240deg fashion, but just
swap two wires on the output and it's all sorted out. :)

cheers,

- Jan

2185. HELP NEEDED REMOTE TUNER & SWITCH

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-20 12:13:13 UTC
From: James Hilins <jhilins@wi.rr.com.REMOVE>
Message-ID: <tfiea.29212$qL4.594976@twister.rdc-kc.rr.com>
Source record: 36788

Hi,
I hope to use the expertise of this group to assist me with some antenna design/work.

Last fall I built a flag pole vertical it is appx 34 feet high, and made of two 20' aluminum flag pole kits from Sams Club. I used appx 5000' of wire to form the radial ground system, and I feed it through a AH4 automatic antenna tuner located at the base of the antenna. (I can provide photos upon request) This easily loads the antenna on all bands 160-6 meters

The antenna has a natural resonance on 40M but needs the tuner for all other bands. The AH4 is only rated for 100W.

HELP NEEDED
I want to replace the AH4 with a matching network capable of handling full legal limit. Currently My plan is to construct a loading coil and tapping it for 160, 80, and 40. 30M and up will need some additional capacitance at the antenna begins to look more and more inductive as you climb in frequency.

What I need help with are design ideas for building a relay network capable of selecting 10 different feedpoints or taps, and perhaps some construction ideas on the loading coil and fixed capacitor choice.

I was going to consider a vacuum variable cap, but after seeing the price I have, reconsidered this and am probably going to look at using a cap from a antenna tuner and just setting it and locking it in place.

Please email me directly with your ideas or suggestions

The best thing is to take the torroid and rewind it for the application you have in mind. The author of the SMPS article in QEX stated that Ai is around 900uH/100t for the torroids in computer supplies.

You can buy a good current controlled switch mode chip for a couple bucks, the FET's diodes and caps are only going to cost a few dollars more (thanks Clint).

Jack

. While you really should characterize the big torroid (by measuring L(uh) at 100 turns) you might be able

Does anyone here in the UK have a minimum of 8 surplus to requirements
TO220 package, 20w minimum 0.5ohm resistors?

Farnel have them but at a heart rendering price.

Far less costly from distributors but I only require a small quantity.

It's well possible I'm missing a major point here, but...

I: 1 1 0 0 (sin)
Q: 1 0 0 1 (cos)

This full 11, 10, 00, 01 count sequence is gone through in a _single_ LO cycle => multiplexer lines are changed at 4 x DDS LO. Like in the Johnson counter setup clocked at 4 x target freq.

No repetitions inside the "11,10,00,01" sequence => each of the four mux outputs will have a duty cycle of 25%, and their frequency is equal to the LO/DDS frequency. That's what is required for the Tayloe detector. I'd think. Probably. ;o)

The AD9854 has one fast comparator on board, so squaring up the other of the I or Q channels requires just one external fast comparator like a 900MHz SPT9689. And then the square wave outputs go directly to the FST3253 mux.

Flames/comments? ;-)

> So how wrong am I?

Yes, there are some problems with that circuit. Have a look at some
other Colpitts oscillator circuits for more ideas. Two things I
immediately notice: as you say, you need some DC path to the grid,
and also, given an implicit B+ bypass, the bypass will short out the
tank with key down.

There are lots of RC oscillator circuits you could use that wouldn't
require the huge inductor, too. If you want to stay with a sinewave,
you could use a Wien bridge oscillator, an R-C phase shift oscillator,
a state-variable oscillator, or a function-generator with sawtooth to
sine converter. If you want something very simple, you can make a
blocking oscillator with very few parts; see for example the
oscillator part of http://www.techlib.com/electronics/rbeeper.htm.
The osc is just Q4, R7, C1, R6, T1, the speaker, and the battery. Put
a resistor (try about 22k-220k ohms...use it to adjust the pitch) in
series with a key between the R7-C1 junction and the negative battery
lead to key it. Or...search through the same (techlib) site for some
other audio oscillators. All these _can_ be done with tubes if you
wish. BTW, another issue is how fast the oscillator starts up when
you key it...the blocking oscillator is essentially instantaneous, but
most sinewave oscillators won't be.

Cheers,
Tom

While the Gingell polyphase networks are an effective
way to generate a broadband audio phase shift, they do
not constitute a fourth method - they are an alternative
for the audio phase shift part of a phasing exciter or
receiver, right along with all-pass filters (e.g. KK7B),
passive networks (e.g. B&W 2Q4) and DSP.

I note that the articles cited in this thread are almost
all old enough to vote. The articles remain interesting
and the theoretical content remains sound, but many of
the issues of the time, like component tolerance and
stability, are non-issues now.

Since you control the detected device, I would suggest the easy way out. Rather than looking for it, trying to see it despite possible intervening obstacles, etc., and the other problems with echolocation, have the thing you're looking for frequently tell you exactly where it is. AX.25 packets containing GPS data - APRS. The software already exists in many forms. One company is making a combo GPS/TNC - just add a transmitter. I'm expecting somebody soon to combine a GPS, APRS-transmit-only TNC, and 150mw 2m transmitter on the APRS frequency. It should be possible to fit that into a 2"x1"x1" 5oz stick, with a patch antenna and a stubby duck, for about USD20/unit. However, I don't know that the demand is there go support the development cost of the ASICS, so your easiest route is probably one of those APRS-enabled handhelds with a cheap GPS unit.

On the tracking side, you'll just need a receiver and a tnc or sound card, and APRS software (free, all over the internet).
Depending on antenna heights, this could work well beyond your 440yd radius. Even just rubber ducks 5 feet off the ground should get you a mile or so in any conditions, and if your fixed station can put a vertical up 30 feet, you should be solid out to 15 miles or more.

I welcome the inevitable technical corrections on range. I don't remember the formulae, so I went very conservative, based on personal experience.

Well, there have been some recent articles mentioned, and
they have been of the practical nature, which suggest to me
that the third method become more a practical method with
recent advances.

It's easy to list a bibliography because relatively little
has been printed on the subject. One can find oodles of
articles on phasing and filter generation of sideband, and
while a few key articles might stand out, generally there's
no problem finding such information. The third method has
always been relatively obscure.

And as I've said, sometimes the earliest articles are more
informative, for the basics, because it is a new field.
Going back to the original articles on the third method
might be more useful than a 1977 article (I just remembered
73 had an article in '77 or 78 on the topic) which is merely
a rehash of previous material, and may have a tone of dismissal
that the original does not have. If people don't grasp the
basics, then they will have a hard time implementing it with
the new advances that likely do make it easier now than forty
years ago.

Well I think you're right Jan. It's the demux internal to the FST3253 that gives the 25% duty cycle.
As far as I can see the Tayloe mixer is simply a neat implementation of two SPDT mixers switched in quadrature.

Can anyone see any reason why the Tayloe mixer would be better than two simple SPDT mixers? It seems to me that as the filter capacitors see the signal for twice as long in the classic mixer and would give similar, if not better, results.
I've built both and I can't hear any difference.

For what it's worth, James R. Hall is KD6JG. He was my immediate manager at RCA Corporation EASD in Van Nuys, California. Now alive and netting regularly from a 5000 foot elevation in central California. :-)

>ii) I have looked at the 1955 paper by Hall and do not understand how it fits
>with the Barber / Weaver configuration. The circuit uses four modulators, but
>appears to require a wideband audio phase-shift network.

It was an audio-range-only method devised at a time when ALL filters and phase-shift networks were expensive and difficult to put together and test...actually about 1954. It took a bit of time before it appeared in the RCA Review.

Jim's reference in a footnote on page 41 of the "Single Sideband Principles and Circuits" by Pappenfus, Bruene, and Schoenike (McGraw-Hill 1964) is not quite correct.

>There is also the 'fourth' method of SSB generation and detection, using
>polyphase networks. You can find an extensive bibliography, and copies of
>papers at Mike Gingell's (now KN4BS, I think) web page at
> http://users.vnet.net/gingell/polyphas/polyphas.html

Heh...I've detected some comments on "nomenclature" of the method. Regardless of such disputes, the Gingell polyphase network represented a major innovation. What I would call a final refinement of the Gingell network appears in QEX, June 1995 issue by Tetsuo Yoshida, JA1KO. Yoshida came up with values which are much flatter in their relative phase shifts over a wider bandwidth. A practical version of that combination is on Hans Summers' website along with the JA1KO paper.

There were several papers of the 1970s-1980s in the IEEE Communications Society Transactions which took up analyses and some slight synthesis of polyphase networks. Those are really only of academic interest now since communications work shifted towards digital time-multiplexing rather than the old "carrier" frequency-multiplexer methods. All in all, the Gingell polyphase is an excellent, value-tolerant network which works for both modulation and demodulation...and it does re-appear from time to time, even in a couple of semiconductor

manufacturer's application notes! :-)

The difference is that the two mixers each will have 4 to 6 db of loss each, plus an additional signal splitter loss in front of that, for perhaps 7 to 12 db of loss overall. The Tayloe mixer does it all in one shot and has only 1 db of total conversion loss, plus off signal rejection capabilities to boot.

I have phased locked a pair of AD9851s to do exactly what you are
talking about here. However, the Tayloe detector seems to be more
sensitive to LO noise than a balanced diode mixer, leading to poor
performance above 14 MHz.

Using a good clean LO, noise is not a problem. VXOs, Phased locked VCOs
or VFOs are a much better LO for this detector.

Every edition of the ARRL handbook ever printed has the formulas for calculating capacitance, and I'm sure it would be on the web somewhere and in hundreds of other books

You will need to measure the area of one plate and the gap spacing between them. Go to the hardware store and buy a set of feeler gauges, the kind that is made of different thicknesses of metal, and use it to measure the spacing. From the formulas calculate the capacitance between two adjacent plates. With the thing completely meshed, count the number of gaps and multiply by the capacitance calculated to give you the total capacitance. This should get you 'close enough' to the maximum capacitance.

Don't forget to include a little bit for stray capacitances, which may be significant on higher frequencies.

Or you could get one of these nifty digital capacitance meters and measure it, which will give you the maximum, minumum, and inbetween values.

Hmmm, I paid a little more for my GR bridge (not the same model, I got
the one with the Omni-null two dial job).
But I think my Heathkit IB5281 is actually easier to use!

Put an inductor of a known value across it to make a parallel LC circuit
then use a dip meter to find its resonant frequency. Then plug in the
formula to find inductive reactance. Since inductive reactance equals
capacitive reactance at resonance, the rest is simple. Go to the formula
for capacitance and plug in the values of resonant frequency and
capacitive reactance.

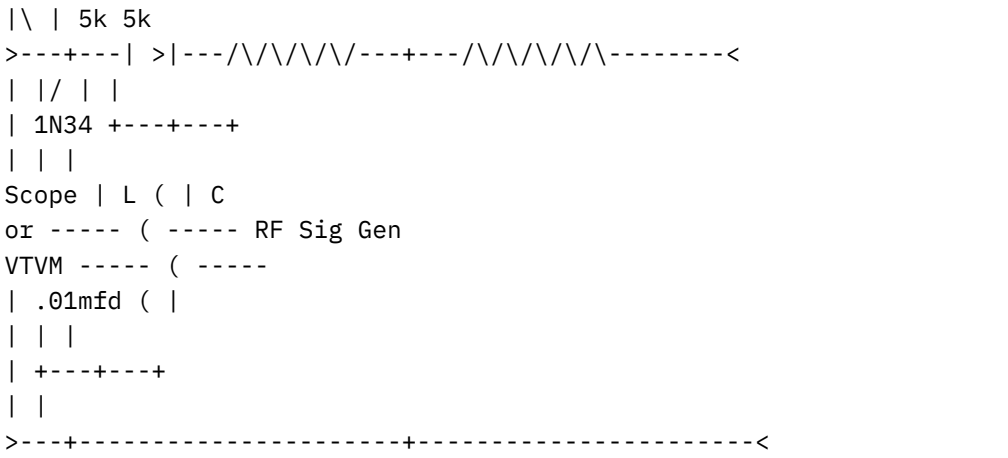
That can also be done with a signal generator and almost any kind of
high impedance RF detector (on a DVM, VTVM, or scope for example).

Wind a coil or grab something from the junk box. Put a known value
of fixed capacitor across it. Then put a sufficiently large (depends
on how sensitive the detector is and how much output the signal generator
has) resistance in series with the signal generator output and connect
that across the LC parallel circuit. The RF detector will peak at the
resonant frequency, and the value of the inductor can then be determined
using the known capacitor and charts. Then substitute the unknown
capacitor and repeat to determine the value of an unknown capacitor.

Here's a circuit:



The 5k values are guestimates, and may not work well if the RF signal
generator output is too low.

> How it performs?

The Rock-Mite is a very limited function rig, because it's bound to just one frequency. (Well, actually two that are close together.) On the other hand, its receiver performance is considerably better than most simple direct conversion designs, because of the front-end selectivity added by the crystal. (One of the two crystals in the Rock-Mite is used as a simple filter; the other is used in the master oscillator.)

It's a toy, not a general purpose radio. But it's a good toy. If you enjoy the game of making contacts with simple equipment, it's a lot of fun. If you like your contacts to come easily, it's not the radio for you.

OK but note that the duty cycle of the Tayloe LO signals is 25% rather than 50% - you will have to square up the two outputs and sum them in a quad NAND gate . But sure - good idea.

Well, I can think of a few ways, any of which *might* be the easiest,
depending on what you have at hand.

1) Use an LCR meter. Very nice to have around. Good for bringing to
swapmeets to ID mystery parts!

2) Add a known inductance to make a tuned circuit and check the freq.
with a dip meter, then work back to calculate C.

3) Add a known inductance to make a tuned circuit and build an
oscillator with it, then measure the freq. and calculate C.

4) Take an appropriate freq. source (e.g. 1 MHz) and feed it into a
capacitive divider, with a known capacitor in series with the
variable. Look at the midpoint amplitude with a scope. Substitute
the fixed capacitor until the midpoint amplitude is 1/2 the incoming
amplitude, then the variable value is equal to the fixed value (+/- a
little bit of scope loading).

5) Look at pictures of known variable capacitors in catalogs, old
Handbooks, or on ebay. You can usually get a pretty good idea of what
you have by looking for something similar.

6) Look on the back and see the value stamped there (hey, it
happens!).

Hi Ken,

You might have a 1650??? They're newer, portable, more compact, and can be carried by one person. The 650 doesn't read as low on inductance IIRC, and may or may not have the 120vac power built in. I think I paid $15.00 for mine on Ebay, got it home, and promptly euchered (sp?) the null meter with too much DC. Now I use a scope for the null.

cheers

I was thinking in terms of the FST 3125 quad switch which does not have a
data selector. If you use the 3253 then the chip itself will do the
selection - I guess this seems the logical choice.
The "Gray Code" issue seems quite important - it can make 20-30 dB
difference in noise according to our experiments.

DigiKey is now making an effort to serve the UK market and will price
in GBP and export. http://www.digikey.com/

They have 20w and 35w TO-220 resistors, 0.51 ohms, but the price may
not be all that much better than Farnells. The 35w jobbies are US$7.78
ea, up to quantity 100, whilst the 20 watt variety is $6.73 in
quantity 1-100.

2222. Choice of standard crystal filter [CW & SSB]

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-22 17:19:52 UTC
From: Richard <nearlynews_email@ntlworld.com>
Message-ID: <b5i5s7$28ufnq$1@ID-150848.news.dfncis.de>
Source record: 36725

One seeks easily obtainable (surplus or new) CW and SSB xtal filters that one can obtain without spending quite a lot of much money. That suggests standard filters. Seems that an HF rig, for IF's between say 5Mhz to 21.4 Mhz, 10.7 mhz xtal filters would I be an intelligent choice. Having in mind getting hold of surplus filters, in preference for new, would going for 10.7 Mhz xtal filters be a good decision? I'd imagine 9Mhz filters are less common. I think xtal filters around 455Khz might have better specs, but you cannot of course get good image rejection for such a low IF. For you that do a lot of homebrew, and use surplus CW & SSB filters, what xtal filters seem to be readily available? 10.7 Mhz ones? Or maybe there are plenty of surplus xtal filters kicking around with some other frequency.TIA. Rich

2223. 13.8V 20A Power Supply from Surplus AT Power Supply

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-22 17:40:18 UTC
From: Paulo Marcondes <pepm@osite.com.br>
Message-ID: <3E7CA002.3DD889E7@osite.com.br>
Source record: 36726

Inspired by some articles posted on this NG (thank God I've got news!)
I'll start modifying a surplus AT power supply to power my IC-735.

Being a licensed ham for more than 7 years now, I was somewhat frustrated for not having much "on air" experience. Now, with this project at hand, I'm felling like a real ham.

I plan to follow the mod scheme in http://www.qsl.net/vk4ba/projects/index.html, as posted past week in the NG.

I'll post project comments, problems and progress here. I expect to be more of the latter.

If anyone do have any comments, suggestions or just wish to say something, please do!

The AT supplies I have are rated 220W and 300W. I'm not sure which one I'll start hacking at first...

I'm thinking that someone is going to say something like,"Yep
there are lots of surplus CW/SSB 10.7 Mhz xtal filters around".
But maybe what's typically easily available are not standard xtal
filters, that were produced for some radio manufacturer.
(Standard xtal filters being those at 455, 10.7, 21.4 Mhz or
whatever is a standard IF).

Or use a high frequency 'roofing filter' and up-convert first, then down convert to 455khz where
mech and pizzo filters are commonly available. For example, 45mhz xtal filters with a bw of about
15 to 60 khz are available (surface mount type from Digikey) which will eliminate a first image
problem when down converting to 455khz. A mixer with good isolation between the ports is required
as the injection frequency is close to the IF frequency. DB diode mixers are good here. A receiver
with no rf stage followed by two DB diode mixers (mini circuits) can have good dynamic range
and selectivity using such a roofing filter and a good 455khz if filter. Surplus Collins mech. filters
or newer ceramic filters show up on ebay all the time. SSB bw of 2.1khz, AM bw of 4khz (or 6khz
for 'hi-fi') are available. Use two if filters with one at the input to the first if, and a second filter
either between if stages or just before the detector for steeper 'walls'. Using two filters will let you
use wider bandwidth while keeping adjacent channel rejection because the 'walls' are steeper.

just my thoughts on the matter.....

For forty years, even a bit more, you could make or buy crystal filters

in the HF range suitable for SSB operation. It was a major leap forward, because you know longer had to worry about image rejection, via heavy front end filters or an extra conversion. It made the rigs simpler

Too much receiver "design" is based on "if this is good, that is better", rather than looking at the specific needs and the tradeoffs. There are good reasons for an upconversion, but there are also tradeoffs. There is plenty of good reason to use a filter somewhere in the HF range. There are tradeoffs, but how serious are they for an amateur receiver or transmitter? Unlike a general coverage receiver, you don't have to worry about holes in the tuning range, and since the ham bands are small parts of the HF spectrum, it is easier to plan around spurious responses. In return, you get a simpler design, in terms of circuitry and in terms of unwanted products, and if someone is just building a single band unit, the local oscillator can be much simpler, since it doesn't have to run in the low VHF range.

As I've said before, if you need multiple bandwidths, for FM, AM and SSB, then you may need to pursue other paths, becuase you can't get the needed filters at the desired IF frequency, or they are too costly. But if it's just an SSB rig, there have been plenty of rigs made with a single crystal filter in the HF range.

If you want to do something tricky, like passband tuning, then I don't think you have much choice but to go to multiple conversions, though I'm not sure the common scheme needs to be followed with modern oscillator schemes.

And Richard's problem, at least up till now, has been that he has been thinking in terms of modifying an existing rig, so he is stuck with the IF that he uses. When building something, one has the luxury of using what's available (issues of spurious responses aside), rather than trying to buy a filter at a given frequency.

So one could go and buy a replacement SSB filter from one of the commercial rig manufacturers, assuming they still have filters in the HF range. It will likely cost a lot.

One could find a surplus filter somewhere. Considering the state of homebrew, is it not possible that there are more than enough SSB filters in the HF range to go around? You use to be able to buy them new, for the purpose of building something. Have they all been thrown out? There used to be surplus SSB filters available, from who knows what source. There was surplus that came from ham manufacturers. Someone took a filter out of their rig, replacing it with a better one, and what happens to the original? How many KVG, McCoy and Snelgrove 9MHz crystal filters are just waiting to be used?

New stock, or new old stock, would tend to be on nice round frequencies. 9MHz most likely, maybe some at 5MHz, and I thought some were made at

10.7MHz. It seems to me that many of the commercial rigs used oddball frequencies, so you'd find 5.xxxMHz filters out of old Swan rigs.

And with the introduction of ladder filter techniques to amateur radio, it seems like crystal filter building has become far more doable than forty years ago when crystal lattice filters were the norm, and you'd have to grind your own crystals to get them on frequency. With a simple design, one could even build a ladder filter at one frequency, and then when a better commercial filter comes along, then do the minor reworking to adapt to the new IF.

There are plenty of good reasons for a single conversion receiver, and once one understands the limitations, they can judge whether it's the best choice. There are also good reasons for a double conversion receiver, in the past due to need, in the present because it brings something that couldn't be done, or done easily, with single conversion. But I don't think it's right to jump to double conversion without spending time looking at the other possibilities.

I'm wondering if anyone has any pointers to code for predicting the field strength of a VHF/UHF signal given power, antenna height, distance, and frequency? Especially in Perl or BASIC but I can deal with C and Pascal.

I've got the FCC's (USA) "Curves" program but it's got a double whammy - it's Fortran (which I more or less knew 30 years ago...) and it's nearly illegible in many places. (it's a scan of a printout...)

Extreme accuracy is not important. Basically I'm wanting to pull data on a station from the FCC database and make a good guess as to whether it's audible at a given location.

I think you will find that there are plenty of 10.7 MHz filters out there, but they are wide as a barn door. Although 10.7 is a very popular IF for FM broadcast receivers, it never seemed to be all that popular for amateur rigs.

I am guessing you'll find plenty of 9 MHz filters out there, and of course, plenty of 455 kHz. If you want a simple design, 9 MHz isn't usually a bad choice. However, if you want steep skirts, 455 is nicer. Unfortunately, image problems mean that you will likely end up with a double, or triple conversion design.

..

Since you ask:

3 or 4 Collins mechanicals plus a few more on boards from transceivers
withdrawn from serviice,
About a dozen Kokusai,
One FoxTango - NIB
One, crystal 2.1, manufacturer eludes me now and its 1am so I ain't
gonna go look it up.
A couple of crystal filters for a 5.1MHz IF by Konel IIRC.

All the above SSB - some USB or LSB; and even a couple of Collins AM
mechanicals.

That's not inlcluding ones currently in use.

Dave

If you have double conversion with say a 8Khz BW xtal filter in
1st RF:

You do not change 1st LO at all when receiving CW, USB or LSB.
So frequency readout stays same no matter what mode.

Using VXO in 2nd L.O. you can place received carrier at any point
within the passband of a 455 Khz CW filter. Or at either side
and with some possibility of variation where the carrier is put
of a SSB filter. The BFO that replaces the carrier for SSB
remains unchanged.

Possibly 455 Khz filters are marginally better then 9 Mhx xtal
filters.

* I think that is passband tuning.

Me again,
Firstly, thankyou all for your help so far.

I'm now looking for any references to using overtone xtals at their overtone frequency for xtal filters. There does'nt appear to be much on the web about it.

I could also use a copy of QEX June 1995 pp 16-21 article entitled "Refinements in crystal ladder filter design" by W Hayward W7ZOI

If anyone has a scan of this article or a URL of its location I would be most appreciative.

cheers and beers, Mike W G8NXD qthr

>
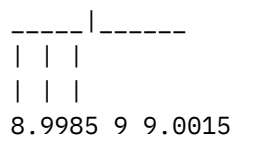
> Regards Max
>
Wait, there can be a mix of how this is specified.

There are plenty filters where the center frequency is specified.
9MHz filters, and plenty of 455KHz filters. There were plenty of
KVG and McCoy filters sold that were 9MHz filters, yet the
carrier crystals that came with them were 9.0015MHz and 8.9985MHz.
The 9MHz was the center frequency, with the edges of the curve half
the bandwidth away. The crystal frequencies sat on the slope of the
curve. Most 455KHz filters are specified the same way. These filters
are suppose to have a symmetrical passband. If you need to switch
sidebands, you switch the carrier oscillator.



But, there are also cases where the specified frequency is actually
one slope of the filter, rather than the center frequency. This would
be the case if there were a pair of filters, one for upper sideband
and one for lower sideband. The carrier oscillator would be right
on the center point. The slopes of the filters would overlap, right
at that carrier frequency. The other edge of the filter would be
the full bandwidth of the filter away, with the furthest edge of
one filter being below the carrier frequency, and the furthest
edge of the other being above the carrier frequency. If you
need to switch sidebands, you switch filters. Or, since filters are
expensive, likely (but not always) this particular rig can do ISB, ie have
a signal on the lower sideband and have a different signal on the upper
sideband.

8.997 9 9.003

Another case for this scenario (though I'm not sure they'd always be specified by the frequency of the bandwidth edge) is if the filter was assymetrical in response. In that case, switching the carrier oscillator to the other side of the filter passband would not provide the best results. One slope of the filter would be very sharp, and you'd place the carrier there, and the other slope would be more vague. So you'd either need another filter for the other sideband, or use some inversion somewhere along the line to get the other sideband.

>
>If you have double conversion with say a 8Khz BW xtal filter in
>1st RF:

Here's another idea, adding variable bandwidth to the variable
passband tuning.

Triple conversion, with only two filters, which could be
anything from 3 to 8 kHz wide depending on whether AM is desired
or not. There would be one filter at each of the first IF and
second IF, and no filter at the third IF,

This will provide, with only two filters, a receiver with both
passband tuning and variable bandwidth, though the narrow
bandwidth will not have the same quality that a separate filter
would provide. (Which might be correctable using only an LC
filter at the 3rd IF, switched in for narrow bandwidth only.)

>You do not change 1st LO at all when receiving CW, USB or LSB.
>So frequency readout stays same no matter what mode.
>
>Using VXO in 2nd L.O. you can place received carrier at any point
>within the passband of a 455 Khz CW filter. Or at either side

The second IF would be near the first IF, say 48 kHz higher.

(That would allow use of 4kHz wide filters at 8 mHz, meant for
telco channel banks. The rest of this description will assume 4
kHz wide filters.)

>and with some possibility of variation where the carrier is put
>of a SSB filter. The BFO that replaces the carrier for SSB
>remains unchanged.

The BFO would be at 48 kHz, with a tunable range equal to the
width of the filters, and additionally would be injected into
the 2nd mixer to move the received carrier to the 2nd IF filter
frequency.

The third mixer would have a VXO 48 kHz higher than the 2nd IF, also with a tuning range equal to that of the filters, making the 3rd IF 48 kHz.

The BFO would then be used with a product detector to convert the 48 kHz IF to audio.

Tuning the 4 kHz range of the BFO would move the received carrier within the 4 kHz filter passband.

Tuning the 4 kHz range of the VXO would move the overlap of the two filters. With the VXO at 48 kHz above the 2nd IF, the two 4 kHz filters exactly overlap and a bandwidth of something just less that 4 kHz would be available. As the VXO frequency is adjusted away from 48 kHz above the 2nd IF, the area of overlap for the two filters is reduced until at 4 kHz higher (or lower), the upper edge of one filter meets the lower edge of the other filter.

>Possibly 455 Khz filters are marginally better then 9 Mhx xtal
>filters.

Some 7-9 mHz filters might be better than some 455/500 kHz filters.

>* I think that is passband tuning.

I've never looked at various filter characteristics to see which filters might or might not be best for such a design. It's just something I've always been going to look at closer and never have. While I mentioned telco voice channel filters, that is only because I'm aware that there must be millions of them available from old analog multiplex systems. I've never compared such things as the skirt selectivity and ripple to modern filters intended for SSB, and that would be necessary before choosing filters.

>
> * I think that is passband tuning.

If you use a 2nd IF VXO so carrier is moveable across the
passband of the filter, I believe that is passband tuning.

However you must have a variable BFO to track with the carrier.
So if normally, ssb signal carrier (if there was one, it's
suppressed) would land at 456.5 Khz, the BFO has to be at 456.5
Khz. Alter 2nd IF VXO so carrier lands at say 456 Khz,
(different place in the passband) you have to adjust BFO to 456
Khz.

> sense I suppose.

Actually if you specify ssb filter frequency as a carrier
frequency of a ssb signal, you could have two carrier
frequencies, one on low side, one on high side. So if center
frequency was 455 Khz how is this described? Either 453.5 Khz
(say) or 456.5 Khz (say). Probably 455 Khz. But that is not a
ssb carrier frequency for a filter whose centre is 455 Khz.
Unless a ssb filter has a preferred side for the carrier and the
preffered side is quoted (Dishal?). Reason I mention this is I
read somewhere about ssb filters being specified by ssb carrier.

Hehe. That is a good one for a 1st IF, real selectivity occuring
at 455. Kinda thing I was musing
over. :c)

Then again, if one could go for the two 9 Mhz filters,
selectivity being acheived at 9 mhz.

One wonders if Mike would sell the 9 Mhz filters. Although I
think I'm tempted to go for real selectivity at 455.

Rich.

Link appreciated - we use this one at work.

Unfortunately..

- I use Linux at home; this is a Windows application.
- I'm trying to embed this algorithm in my own program. (i.e., I need
the source code. Or even just the formulas.)

I'm tempted to just start typing datapoints from the F(50,50) curves in
the FCC regulations and create a lookup table... or see if I can get
"wget" to throw the appropriate parameters at the online version on the
FCC website & create a lookup table that way...

It sounds like your local suppliers may all order from the same source.
Opening a European catalog finds several different sources for the whole
range, in different styles and quality.

The one that *is* becoming hard to find is the 8-pin "horseshoe" type,
as used by Yaesu transceivers for the BAND DATA/PTT output. In Britain
we seem to be down to one supplier for that, and I've never seen a
metal-bodied version.

2258. Tayloe Mixer and "Gray Code" noise

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-23 18:04:55 UTC
From: Richard Hosking <richardh@iinet.net.au>
Message-ID: <3e7d1672$0$3756@echo-01.iinet.net.au>
Source record: 36741

Dear all

I am in the process of designing a general coverage SSB TX/RX based on this mixer using a quad bus switch
-either FST3125 or FST3253
I have been working with Rod Green VK6KRG
We have found a dramatic difference in the mixer noise between two designs - in the order of 20-30 dB
It may be other factors, but among other things one of the differences between the two prototypes was that one quadrature mixer used a "Gray Code" sequence in the LO and the other didnt
A standard 2 bit binary sequence is 00 01 10 11 - this is what is generated by a 74161 or 74163
Note that both bits change state between 01 and 10 - my thesis is that there is transition timing jitter varying between the two gates and this mixes together to produce noise
If a "Gray Code" sequence is used such as 00 01 11 10 then this effect should not happen.

Has anyone got any ideas? Is this a real problem?

I plan to use a 74AC74 as a Johnson ring counter and use this to drive the 2 bit address selector of the FST3253. This will produce a divide by 4 quadrature LO.
I would be interested if anyone is doing a similar project.

Richard

Have some brand new, Centralab transmitting capacitors for sale. Model is 857, and are rated at 200 mmf at 7.5kvdc, N750. Can mix and match these values for coupling capacitors, padders for loading capacitors, or what have you. $5 each plus Priority Mail shipping. I cannot ship outside continental US.

73s,

Evan

True, though that doesn't solve the issue of embedding the results in my own application.

What I ended up doing...

is to use the LWP::UserAgent module to pass the appropriate parameters to the online calculator on the FCC website. I then parse the resulting value out of the returned HTML page. Rather slow (and I kinda expect to get an email from the FCC webmaster tomorrow asking why I'm harassing his server<grin>) but it does work.

I'm also caching the results in a MySQL database table. When the next station is looked up, if the same ERP/HAAT/distance values are already in the local database then there's no need to run the calculator on the web.

Not 100% sure the caching is working yet.

You should be able to find lots of them in manufacturing and the
chemical industry as young as 40. Probably not a lot younger than
that. Although they do make it a lot easier to amplify a signal from
a thermocouple. Now days you do it with solid state switches.

while doing research on mobile antennas
for my automobile, the thought has occurred
to me that it was theoritcally possible to tune
an antenna using a permeability tuned coil
much like using a permeability tuned vfo.
since i have not seen such an antenna,
the question is why is it not done? to expensive?
not power handling ability? or what???

My recollection is that HP made an expensive and very sensitive meter that used a nice mechanical chopper in it. I think I remember having one on my bench for a few weeks in the early 1960s.

That was the model 412A. It used a rotating disc driven by a clock motor, some incandescant lamps, and some cadmium sulphide cells. Worked fine if adjusted properly. I still have one and still use it.

YES, you're bringing back memories. I'd love to have on these days.

I still remember the shock when the meter movement was damaged and had to be replaced and the cost was, in the early 1960s nearly $200! I sure loved that beautiful big mirrored scale though.

I owned something (fluke?) with an analog meter, and a current/volts setting.

It used neon lamps to do the chopping. Someone stole all the transistors, and all that was left were sockets. I measured and tried surplus transistors until it worked, and it did. The needle wasn't entirely stable (noise?) but sensitivity seemed to be okay, it could measure a permanent magnet moving fairly slowly across a single wire quite well.

Later I gave it away.

Thomas

Latest list of stuff asof 3/12/03
Kinda long but bear with me...

All used unless stated NOS/NIB
*** All prices are POSTPAID lower 48 ***

---Tank coils---
Heavy-duty Air-Dux 195-1 PI NET coil
Plated strap 10M coil, 10T 4 TPI and 9T 6 TPI of No 10 wire
Total L 20 uH, 6 factory installed taps
Easy KW plus, looks unused $62

---AF xfmrs---
NIB Triad A-35A 10K plate to 90KCT single or P-P grids.
Unused. Allied catalog says freq response 50 to 10K.
2 x 2 x 2.5H inches. $32

2 each NOS Stancor WF-30 multi-Z interstage AF xfmrs.
Hermetically sealed. 1.5 x 1.5 x 2H inches. $13 ea

---coax relays---

These are Danbury-Knudsen or FXR, silver-plated, flat to 600MHz+,
100W+, BNC coax jacks. See old Allied/Newark catalogs.

FXR, NOS, SPDT, 115VAC coil, 2 x 1.5 x 1 inches, $16

D-K, used, SPDT, 18-24VDC coil, 2 x 1.5 x 1 inches, $16

D-K, used, SPDT, 12VDC coil, 2 x 1.5 x 1 inches $16

D-K, used, SP6T, 12VDC coils, 3 x 3 x 2 inches, $25

Motorola, NOS, SPDT, 6VDC coil, 3 x 2.5 x 1.5,
Ant and Rx BNC, Tx solder terminal, $12

---tubes and sockets---
Eimac SK-610 4X/4CX family socket with mounting tabs. $12 ea
Good low-mileage 4CX250B with above socket. $27

Set of 10 real stetite sockets with snap rings
6 4-pin Amphenol, snap ring mount
4 octal Amphenol, snap ring mount
Some new, some used $14 all

---solid state tube-replacement rectifiers---
2 each NIB Sarkes-Tarzian S5251/1N2389, 1600 PRV, 600ma
OK for all except 5R4
$12 ea

1 each Semicon.Inc 1N1239, 2800 PRV, 500ma
OK for all including 5R4
$12 ea

---filters---
Stock Drake 4-line C-F Networks xtal filter model 5645-2.4L
with carrier xtal 5644.999KHz. $35

Kokusai 455KHz 2.1KHz xtal filter model 455ZU-01H
Hermetically sealed. $17

---xtals---
38.1MHz xtal for Drake 4-line. $6

1 lot of 5 HC-6 xtals. 3.4, 10.4, 17.4, 23.4, 24.4MHz
$16

1 lot of 4 HC-6 xtals. 1.545, 4.545, 15.545, 22.545MHz
$14

You mean to tell me that for $25 I don't get a rig that's as rock
solid as the FT817? Man, what a gyp.

Back to reality...I have both versions, they are a lot of fun to
build, more fun to operate, and LOADS of fun to run from the trail or
campsite.

7040 or thereabouts ALWAYS seems to have someone standing by ready to
QSO.

73

Face it, anything else that gives you this much fun for $25, is
probably illegal and unhealthy.

The core loss would be excessive. That's why all RF power inductors have air cores.

Certain materials have sufficiently low loss, but they tend to get expensive.

Maybe it was a 412A; they were sold in the mid-60s. It was a DC VOM
with voltage ranges from 1000 V to 1 mV, and essentially zero drift.
It used CdSe photocells as both the input chopper and the final
synchronous demodulator, with a tube AC amp between. It used a
synchronous (clock-type) motor, a light bulb, and a chopper disk to
drive the photocells. Very nice instrument.

The early Fluke and HP differential voltmeters used mechanical,
vibrator-type choppers. Choppers were widely used in servo systems.

Lots of people make CMOS IC chopper opamps today. Some have drifts
measured in nanovolts per degree C.

Source record: 36692

There was very recently some discussion about permeability tuned
inductors on either this group or rraa, I don't recall which. From that,
I gathered that no one has seen a powdered iron rod except for the cores
used for small variable inductors. Certainly a powdered iron core of a
size useful for tuning a mobile antenna for transmitting purposes would
be very expensive if you could find one at all (which I doubt you could do).

The recent thread also showed that quite a number of people don't know
the difference between powdered iron and ferrite (and some don't seem to
be interested in learning), and think their ferrite rods are powdered iron.

One problem with using powdered iron for tuning a solenoidal inductor
(if you could find the material in rod form to do it) is that you
wouldn't have a great deal of tuning range. The permeability of powdered
irons having low loss at HF is quite low, and the large air gap in the
magnetic path would make the effective permeability lower yet.

A high frequency ferrite such as Fair-Rite 60 series might be practical.
But you'd still need a large inductor to get good Q, and then need a
very large core to be effective. It would be expensive.

>
> Has anyone got any ideas? Is this a real problem?

This is partly on-topic, partly off-topic, but...

http://www.arrl.org/tis/info/pdf/030304qex020.pdf
(btw, also see www.flex-radio.com)

which is a paper by Gerald Youngblood about the hardware part of a
software defined radio, a balanced 2 x dual-mux Tayloe transciever.
Maybe you've seen it already?
It seems the author didn't realize it, but his setup uses Gray code for
the dual mux (PI5V331 which is quite similar in specs to the FST3253) -
and in the paper he also presents some measurement on how well it
performs, IIRC. Maybe you'll find it useful as a reference...

good luck,

73,
- jfw

hi there..

can anyone tell me the max power rating in watts (continious) at 2m thin 50r (like rg174) ptfe min coax will take safely. I am making a wilkinson combiner and need to connect it to the outputs of the amp modules, and would like to use it rather than rg213 etc.each length will only be 150mm (6in) max..
the amp is made of 2x300w modules..

thanks simon G0ZEN...

p.s. combiner is using microwave copper sheaved 75r semirigid..

Hello

> can anyone tell me the max power rating in watts (continious) at 2m thin
50r
> (like rg174) ptfe min coax will take safely. I am making a wilkinson

The RG174 (standard) is rated 95W at 144 MHz

The RG316 (PTFE) is rated 240W at 144 MHz

Regards Max

Yup it's a 1650A. The null meter works fine, don't know how you blew
yours up.
I only run mine off the internal batteries. I have a hard time
measuring L with it,
I can find several null points between the two dials, and you have to
have the range
switch in the right ballpark to start with. I don't know how low in
inductance it goes,
but it measures large filter chokes (several hundred henrys) ok.

I'm tempted to buy his pre-programed pic controller to install in a home brew rig of my
own design, or to just use it as a keyer. I have some NE602's, wonder if they will sub for the '612.
BTW I heard that 3.579mhz (color burst freq) is used as a QRP calling freq on 80, is this true? (cause
I have a few of those rocks). Any opinions on which band is better 40 or 20 (or 80)?

The only difference between a 602 and a 612 is that 602's are 100% tested (and thus a little more expensive). I don't know why one would choose Dave's chip over any of the other keyer chips if you were interested in a keyer. And yes, 3.579 is a popular QRP frequency.

What band is best is one of those questions where the answer is "it depends". But if you are rockbound with low power, I'd choose 14.060. 80 is tough on QRP, 40 has plenty of QRM so a fixed frequency is a real challenge. 20 is QRP friendly, and you can always kick up a QSO on 060. BUT, if your operation is mostly late at night, maybe 40 is a better choice. 20 shuts down, especially in the winter, and as the spots fade, it will shut down earlier. Still, assuming the wa2 means you are a right-coaster, 40 could be a real challenge.

There you go again Brian, trying to sound knowledgable about things of
which you have little understanding.....

Core loss for any given material increases with both the frequency and
the AC flux densitiy (in this case, RF power). Some iron-powder core
mixes have a very low core loss even at high frequency, and most are
available as threaded cores. Also, permeability is usually sacrificed
for low core losses at high frequencies, but that shouldn't be much of
a problem since you just want the core to tune the antenna and not
necessarily to load it, and you don't need much u at high frequencies
anyway.

I would recommend you get some literature from here:

Guys and gals,

Does anyone know where I can get a 20 henry, 500 ohm filter choke? Im wanting to start building the first set in the "Radio For The Millions" book. I can get everything else either locally or online, but not a friggin 20h 500 ohm filter choke.

Anything that could be easily substituted for it?

Jeremy

I'm 49 and I know of them. In instrumentation amplifiers, they are used to modulate the input voltage after which the modulated signal is detected as a D.C. voltage with an offset determined by the precision of the match of the two choppers. At the time, the precision D.C. instrumentation amplifier did not exist.

Good, but strange. I was on a service call one day, and this little
old lady answered the door. She told me she had a dog, but he wouldn't
bother me, and would hide under the couch, till I left. It was a toy
terrier that looked exactly like my 40 pound terrier at home, but it
could sit in the palm of your hand. i got busy on the TV, and heard the
dog's toenails on the hard floor and looked up to see it had brought me
one of its toys and laid it by where I was working. The lady was
shocked. She went on and on about how it had never taken to a stranger,
and never let anyone near any of its chew toys. I smiled and told her I
had one of my own, and it probably smelled the scent and knew it was OK.

I miss that old dog. He started having strokes and the vet couldn't do anything, so we had no choice but to let him be put to sleep. I doubt I'll ever see another one like him again. He wasn't afraid of the biggest dogs in the neighborhood, but would lay by the couch and watch a baby sleep and come get someone if it moved. He was terrified to climb stairs, but would jump up on things a lot higher. If I carried him down into the basement he would sleep by my feet while I worked all day at my workbench. The strangest thing was when he was a pup a cat attacked him, by slapping him with a paw, and those nails extended. Instead of jumping it like a dog would normally do, he slapped it, and it rolled about 20 feet across the yard and never came back. He was a strange, but lovable old friend.

Hi,

Various application notes have warned me not to use sockets for high speed analogue ICs, but alternatively use a Minimount system: http://www.rdi-wainwright.com/

I'd like to hear from anyone who has had experience with these as there is little information on thier website or in the newsgroup archives. My application is testing 10 of my own custom 68pin PLCC analogue chips at clock frequencies up to 300MHz, with rise/fall times better than 1ns. I'm not too keen on soldering 10 chips on and off my pcb.

How are the minimount systems removed from the PCB? Is it easy to remove the excess glue so that another minimount can be placed? Is there any soldering associated with minimount replacement and is it much easier than removing a 68 pin plcc?

How much extra room on a PCB does the minimount take up and what typical inductance does each pin see? Is there really significant inductance saving over a surface mount socket?

Has anyone tested the difference between the 0.8mm and 1.5/2mm minimounts? Is there a significant frequency improvement with the thinner boards and how much more difficult are they to work with?

thanks,

Alistair McEwan

They used to use these sometimes for RF prototyping where I worked, once. I
liberated a couple, but never used them.

I needed something like them once that wasn't in their range, designed my
own and had a few made. I sold the ones I didn't need - paid all my costs.

The adhesive seems to be similar to double-sided tape, and should be easy to
remove. Ease of replacement depends on how the Minimount is connected to the
rest of the circuitry.

>

There is probably a lot more stray inductance and capacitance, because of
the additional track length added to the leads.

The mounts I had made were 0.8mm thick. I had no problems with them.

rec.radio.amateur.misc]

Hi,

I'm thinking about changing my NiCd cells in the battery for my Yaesu FT-50 Handheld to NiMh type instead. Mainly for 2 reasons:
1) larger capacity and 2) the old ones cannot hold their capacity for longer periods of time anymore.

The battery is of the type FNB-41, 9.6 Volts and 600 mAh. I don't know about the number of cells, their size or voltage, but i bet it is 8x1.2 Volts.....

Does anyone have any experience in opening the battery case for this particular type of battery? I have an idea about the casing being welded (melted?) together rather than glued, and i don't want to break it if i can avoid it or it is a waste of time to try.

Ideas, anyone?

Also, if anyone have any comments on the internal charging circuitry of the FT-50 (if it can charge NiMh or not)... i would be grateful.

I changed my battery to the NiMH FNB-41 recently and I love it. And I
had the same ideas about cracking open the case and such. But before I
did I did a search the web and purchased one for less than 1/2 the price
(including shipping!) than I could get it from our local ham store.
Check out www.pandacomm.org.

At that price it was not worth the hassle for me.

Haven't tried it myself, but I've heard that putting the battery pack in a
freezer for an hour or so weakens the joints, enabling it to be easily
opened.

>an antenna using a permeability tuned coil
>much like using a permeability tuned vfo.
>since i have not seen such an antenna,
>the question is why is it not done? to expensive?
>not power handling ability? or what???

First of all, as Roy Lewallen pointed out, the inductance variation wouldn't be large. Core-in to core-out of either powdered iron or a brass slug is roughly 3:1 inductance change, maximum (for power-handling apps). That might be nice for a single-band installations or maybe two bands having close geometic frequency centers.

Second, there's a matter of practicality. In a mobile installation it's a lot of trouble to have variable components and their moving parts (gears, motors etc.) both in a "hostile" environment (rain, snow, etc.) and needing power...plus the servo control in analog form rather than digital.

Countering the "core losses," simply check out the modern step-selected fixed inductors in modern automatic tuners: Toroids wound on powdered-iron cores. No problems...those can handle 2 KW or so from several ready-made AAT manufacturers. As toroids, they can be packed closer together with minimal effect on neighboring components and with minimal EM fields around them.

The step-sequence inductances and capacitances of modern AATs are relay-selected with a wider range than physically-variable L or C. Steps in a 1-2-4-8-16-32-64-128 sequence are more easily selected digitally with a resolution equal to 0.4% of full scale for a binary sequence of eight (as illustrated). Relay contacts may be sealed from the environment, have very high "off" resistance and very low "on" resistance (perhaps better than the roller contact on an old variable inductor system).

The arguemnt of needing "infinite" variablility via analog tuning has no good argument since the actual tuning of nearly all AATs, analog or digital, is broad enough that fine resolution is not "seen" by any antenna tuner. Step-increments are just fine - as proven - over the entire HF range and a bit beyond (most go down to 2 MHz and less). The SGC line of automatic antenna tuners is a good example, used

as easily in non-amateur antenna tuning applications over HF.
A digital step-selection L and C AAT can be automated by a 1-chip micro (perhaps with relay coil drivers outboard...depends on relay coil requirements...no problem since they operate saturated or cut off) or operated remotely by a "human microprocessor" through several ways.

If an antenna tuner is slightly off its optimum setting, there won't be any discernable variation in signal strength coming or going. That's analyzable many ways too, but takes some skull sweat and time.

I used one of the Fluke differential voltmeters when I was in the army.
Today, people just don't appreciate how much time and labor a DMM saves
them. Give them a differential voltmeter to use, and let them realize
how it's done, manually.

Let's not forget Ballantine Labs. There was a very good true RMS analog meter that used a mech chopper amplifier to handle the output from the tunnel diode detector. 50 to 500 microvolts DC, not easily done in the 60's. Also a mechanical DVM, that used a chopper amp as the servo. Noisy but quite accurate.

Don't get me wrong, Dave is a great designer. But his design is for a more or less minimal keyer, with some other control functions as well. Likely you won't use those other functions. There are several keyers in 8 pin packages with a variety of capabilities and a range of prices. The TiCK is the most popular, although I understand delivery is a bit slow lately. The TiCK-1 is the basic part, the TiCK-2 adds 2 message memories, and the TiCK-4 adds nonvolatile parameter storage (a must-have in my book!) The TiCK-3 is available in surface mount if you want tiny. There are also keyers from Harbor Beach and N1EL (I could be off a little on these names) that have additional/different features. All are 8 pin DIP formats. The TiCK has a speed setting scheme similar to Dave's, I think it's the Harbor Beach where you add a pot to set the speed instead. If you don't mind an 18 pin package, you can easily roll your own from a PIC and get your favorite feature set! For instance, I found that I REALLY preferred the scheme on the K1 where you have up and down speed buttons and an LCD display of the speed selected. So I programmed a PIC to do that. (Not for sale but I'd be happy to share the code).

> East coast yes, but SOUTH not north. I'm in the FT
> Lauderdale area.

I was thinking east more from the standpoint of European broadcast QRM than NYC QRM. Frankly, I don't know what sort of a problem that is in FL. However, farther south, 20 is a better bet because it stays open later, although you probably won't get the late night over the pole stuff we get up here in the frozen north.

A much more important spec for this choke than its resistance is its
saturation current. Can you calculate how much current this choke
must pass without saturating?

2329. Keyer circuit for IC-735 (does anyone know another?)

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-26 01:21:23 UTC
From: Paulo Marcondes <pepm@osite.com.br>
Message-ID: <3E810093.F58ACF55@osite.com.br>
Source record: 36632

Well... with the AT power soucer conversion on its way,
I am thinking about a eletronic keyer for my IC-735, since I
plan to op CW but am not willing to pay many bucks for a
ICOM one.

Some time ago, I've found this circuit on czech web page.
The english is very crude, but he translated upon my
request, so... i can only thank Karel for the effort.

http://ama-cb.nagano.cz/IC735_elbug_eng.htm

I would like if anyone can send their comments on this
particular circuit or have another one at hand. I may even
build many and try what suits me best. An extra would be if
someone points me to a IC-725 keyer circuit, for the group's
radio.

Thanks

In the sixties, I used an analog computer which used chopper stabilized
amplifiers as op amps. We used it to solve simultaneous diffential
equations. It took hours to program with patch cords and to adust
coefficients, but it took only a couple of seconds to print out the
solution in the form of a graph on graph paper. The computers were made
by some company in New Jersey whose name escapes me now.

Precision Analog Computing Equipment (PACE)
Long Branch, New Jersey

I'm holding in my hand one of their plastic templates to draw the analog computer blocks. I've had it in my desk drawer for all these years 40+ and another at work and I still use it for simple drawing in preference to a ruler and used to have a second one that has escaped over the years. I think somebody lifted it from my desk at work.

I loved those computers and would much prefer to work with them rather than those klunky (at the time) digital things that never worked for longer than a half hour or so before having to be repaired. I used it at grad school at Northwestern in the 1959 and 1960 school years. And wasn't that a wonderful Non Linear Systems (San Diego) digital voltmeter with the stack of engraved Plexiglas digits edge lit for a readout great and impressive?

There was something very satisfying about tweaking a coefficient pot and watching the trace on the strip chart change in response as the red ink splatter from the pen left a track across the front of your shirt if you were impatient and opened the cover while it was still running.

Besides sitting in front of the computer with all those ten turn pots (a couple of hundred in a top end system) and all those plug in amps was sort of like being in command of a spaceship or something or so it seemed in those naive times.

Of course Northwestern's other Analog computer, circa 1945, took up a whole half of the room and a full wall with full size inductors, capacitors and the like. I never saw anybody using it.

Memories...

In the sixties I maintained a big analog computer (tube based) that had
motor driven chopper stabilized op amps.

It too solved simultaneous diffential equations, though the solutions
were in real time.

The problem was hard wired and there were these huge (feet in diameter)
oil filled servo driven pots to derive a solution.

It was the fire control computer for the Nike Hercules anti-aircraft
missile system.

My fondest memory is hot swapping a bad op amp one day (you weren't
supposed to do that, but this was not in the US and aircraft with
red stars were heading our way) and getting knocked to my knees by the
charge in one of the B+ caps. Turned out the bleeder resistor was in the
mainframe, not in the op amp itself.

I've done it several times to FNB-4A packs. Freezing helps,
but in the newest of my packs, Yaesu used a *lot* more
glue, making it very difficult to open without slight damage.
Maybe they want to discourage replacement of the pack?

My experience with the NiMH cells is that they self-discharge
much faster than NiCd batteries. Also, it seems that they
are a bit more fussy about charging. Maxim makes several
chips specifically for NiMH batteries, and I may build up a
charger using one.

Hi, G1HSM,
Thanks for the tip. I think i'll try it out soon.... because by now the battery seems to have died completely. I haven't tryed to boost-charge the NiCd-cells yet or anything fancy, mainly because i still want to improve the capacity of the battery anyway.....

Very nice project, altought I haven't analyzed the circuit in details. I own a IC-728, and I guess also the 735 works only with vertical keys. Anyway, any keyer circuit is good for any radio, I'd say: look on Internet for the circuit that is easier to build for you!

I have personally built this:
http://digilander.libero.it/vcoletti/pic/keyer/index22.html

but you would need someone to program the PIC. I have also found this project by Harry

http://w1.859.telia.com/~u85920178/use/simplek.htm

but never tried myself.

Yes!!!! I think it was close to Fort Monmouth where the army did
electronics research. I also remember Long Branch as being a resort town
and sorta unusual for the location of a then high tech company.

I remember how happy my EE professors were when they got their first
rack mounted digital computer. The students weren't allowed anywhere
near it. We had to use the analog computers.

Check http://www.embres.com/tick.htm .

These keyer kits are easier to build and have a lot more features. But, OK1RR's circuit costs less money to build.

Any keyer made for a radio without vacuum tubes will work with any other radio without vacuum tubes. So the OK1RR circuit will work fine with the IC-725. The "embres.com" keyers will also work fine with the IC-725.

I hope to QSO you on 28MHz CW soon!

Yes! The guy I worked for got one surplus, something was wrong with it.
It rattled a lot as the relays hunted for the input voltage. I don't
remember if it was a NLS, but it had those plexiglas edge-lit digits,
and it was a trip to watch them thru the windows. NLS later started
KayComp which became Kaypro Computers. I believe the guy's name was Kay.

I hope you're saying fondest memory in jest, because I wouldn't consider
getting knocked on my knees a fond memory.

I worked on the Nike Herc search radars when I was in the army. I
didn't get a chance to see any of that fire control stuff.

Seems hard to believe that what they used back in those days took up a
whole room, yet today could fit in a pocket, or even a wristwatch.

2348. Am I using the wrong ferrite cores?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-26 16:41:05 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0303260841.98fb276@posting.google.com>
Source record: 36550
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

Can anyone here tell me if I need different ferrite cores? The SWR meter I am working on seems to work OK on the lower bands but does not work on the higher bands. I don't think I have any stray capacitances or inductances in my circuit. (This is HF, not VHF, UHF, or microwave.) However, I do understand that ferrite cores have their limitations, and I believe those are the source of my problem.

The design I am using is based on that portrayed in the last of the three schematics at:
http://engphys.mcmaster.ca/~elmer101/rfpower/swrtheory.html

One difference between my design and that one is that I apply an RC low-pass filter to the diode outputs consisting of a .001uF capacitor and a 100k-ohm resistor in parallel.

The ferrite cores I am using have #43 type material. The dimensions are .5-in. thickness, .625-in. outer diameter, and .3125-in. inner diameter. The turns ratios are 1:10 for both. I noticed that most of the other SWR meter designs use smaller cores. (I'm wondering if I have stray capacitance between the primary and secondary wires due to the relatively long length of wire my cores use as compared to the wire lengths of smaller cores.)

I tested my design by connecting it to my transceiver and dummy load. The dummy load is supposed to be 50 ohms, but it has stray capacitances in parallel to the load, and this causes the SWR to go up as the frequency increases. I used full power in order to minimize the effects of diode losses.

At 1.8MHz, my MFJ SWR meter showed an SWR of 1.9 and 60W of power. The forward voltage sample is 6.46V DC, or 10% of the actual forward voltage. The reflected voltage sample is 1.707V. This gives an SWR of 1.7. Considering that the MFJ SWR cross-needle meter has mediocre resolution, these results seem reasonable.

At 3.8MHz, my MFJ SWR meter showed an SWR of 3 and 20W of power. (As you can see, the high SWR protection circuit in the transceiver was at work to limit transmitted power when the SWR is high.) I had 3.578V forward, 1.795V reflected, and a measured SWR of 3. So far, so good.

At 7.2MHz, my MFJ SWR meter showed an SWR of 5 and 15W of power. The measurements were 2.838V forward, 2.166V reflected, and an SWR of 7.5. Considering the awful resolution of the MFJ meter at high SWRs, this seems reasonable.

At 10.12MHz, my MFJ SWR meter showed an SWR between 5 and infinity. The measurements were 2.941 forward, 2.673 reflected, and an SWR of 21.

Around the 20m band, my SWR meter begins to fail. At all higher frequencies, my MFJ meter showed 10-20W of power and an extremely high SWR. The forward reflected power drifted down from 2.692V at 14.3MHz to 1.5V at 29MHz. At 14.3MHz, my reflected voltage was 1.3% HIGHER than my forward voltage. At still higher frequencies, my measured SWR actually dropped.

My measured SWR was infinity at 14.3MHz, 89 at 18.1MHz, 13 at 21.3MHz, 5.7 at 24.9MHz, and only 3.9 at 29MHz.

Can anyone help me? Do I need a smaller #43 core? Should I switch to a #61 core?

YOu need a beter dummy load to do the tests. YOu should be using a good dummy load and to get the swr parallel 2 or more good 50 ohm loads. Then use some capacitors or inductors and calculate the swr of the load.

Also you could probalby use a beter standard than the MFJ sutff.
I bought an antenna tuner made by MFJ. I did recaliberate the wattmeter against a Bird and a surplus wattmeter. The MRJ was a bit off from the other 2.

It is difficult to do lab quality measurments with low quality equipment.

>
>Can anyone help me? Do I need a smaller #43 core?

Hi Jason,

You decide your design is faulty because it cannot measure a very poor load at high frequency. Faulty logic and poor technique is closer to the problem. Am I to believe that this extremely poor load is your dummy load with stray coupling??? Or is it simply an extremely poor load? Why? Don't you think you should see if it worked with nominal first? Don't you think that calibrated mismatches rather than opportunistic SWRs would help resolve your issues? Consider the question and ANY answer: you could have answered it yourself if you had simply observed my comments long ago about buying several formulations and forms and substituting. That path to a solution would have taken perhaps twice as long as the time of your having written a plea for someone else to do it for you.

Beyond that, how is it that the core becomes suspect because the circuit failed? Jason, you are not showing much savvy in the lab by skipping the fundamentals. This is poor second year lab stuff, not graduate quality. Do you have an adviser or thesis reviewer? Fire same, they clearly have no interest.

|Can anyone here tell me if I need different ferrite cores?

Maybe, but how can you tell with the measurements you are making.

First you need a precision termination and some known mismatches for
standards. Some precision attenuators followed by a short will give
you known return losses.

These need so be in the same connector series as your test port, which
I hope isn't an SO-239. No adapters allowed.

Trash the MFJ. Do not try to measure one unknown by comparing to
another unknown.

Isn't this a school project? Don't you have access to a real lab?

Treat this as two projects. Eliminate the detection process until you
get the power sampling down. Your two transformers are just a 20 dB
bi-directional coupler. Measure its parameters separately using good
terminations all around and find out how it functions.

When you've got the coupler working, move on to the detection process.

Picked up a transformer that I want to use in my radio power supply
but I'm having a little trouble identifying all the leads...

It has 4 leads on one side which I have ID'd as low voltage outputs...
.3 and .4 ohms respectively. On the other side I have two leads that
are 115v 11 ohm input leads. Then I have two high voltage 600v outputs
with a 300v centertap. I then have one lead left over that dosen't
seem to be tied to anything using my ohm meter. Does anyone have a
clue as to what this lead is for?

thanks,
Tracy

They trained you to work on RADAR? They pulled me from the Weather
Vision section at Fort Rucker and sent me out to fix RADAR equipment
with no training. Of course they didn't train me to work on the CATV,
video, or microwave CARS equipment either. A draft notice, a MOS test,
and I was a broadcast engineer.

You could try using one of the small clamps available from RS
Components. The clamp Im thinking about has a nylon screw to set the
height and allows the lever to latch over and clamp the DUT positivly
onto the pads on the PCB. Ive used this on TSSOP chips and it is a
little bit fiddly to line the pins to the pads, it works amazingly
well. Plus its cheap,available and reusable.

The extra trace length of a socket compared to a clamp may or may not
be an issue, plus any board deskew you may need to add if you are
attempting to measure very accuratly. Figure about 6 pS per mm.

Hey guys....

I have some logging equipment that I'd like to make a "stand-alone"
display/terminal for.
At the moment a pc/laptop has to be plugged in to the equipment and a
terminal program is ran to view the data.

I'd like to build a display that will receive the data in to bins and then
display on to either led/lcd screen (led easier to start maybe).

Looking at things....I think I need to use a UART 16550. Which, correct me
if I'm wrong, converts rs232 to TTL....then I'm guessing I could put that in
to a buffer/register/sequencer....basically store the info (how would I
step/clock this in).
Then I could take the byte word and parallel output it to display drivers
w/buffers and display the data until things are updated again.

Thanks

Depends... if you get an LCD with a controller, it can be easier than an LED display.

The UART converts parallel to serial and back.

A line driver converts levels.

Hi,

My FT-50 is an early model, and the battery is probably just as old.... so I hope that they haven't glued it too much...
In detail - how do you open it ? I thought about running a knife or so along the assembly edge all the way around and then try to get a screwdriver or similar inside.... is that the procedure ?

I did a bit of surfing around to find alternatives to replacing the cells..... take a look at this:

http://www.mahaenergy.com/products/radios/nimhbp/yaesu/index.htm

One question comes into my mind: These battery packs - the cells inside - are they type AA or type AAA ? -it seems to me that the slim outline of the pack might not be wide enough for a type AA cell ?

If they really are AA, it seems that I can build a new battery pack on just about the same capacity for somewhere around 2/3rd of the price, at least when I convert it into Danish currency and account for overseas shipping...
-But as you mentioned, Leon, I might need to add a new charger circuit to make really good.

> if I'm wrong, converts rs232 to TTL....

The 16550 handles the RS232 protocol. You need an additional chip to
convert rs232 voltage levels (typically +/- 12V) to TTL. In the old days
the 75188/75189 chips were used. Nowadays chips such as MAX202 are used
because they have their own +/-12V generator.

then I'm guessing I could put that in
> to a buffer/register/sequencer....basically store the info (how would I

>
>

The 16550 has a 16 byte fifo (first in - first out) buffer for incoming
data. You will need to configure the 16550 by initializing 10 or so
internal registers. This is best done by a microprocessor. Otherwise you
will need a forest of TTL chips to do it!

This would be a good project for learning microcontroller design. Get a
low cost microcontoller evaluation board and write the terminal program.
Select one with an RS232 interface. Some of them have a built in display.

You can buy LCD displays with an attached uC (PIC usually) which take in
RS-232 and display the data. They are quite cheap.

It should be grounded, and goes between the mains winding and the others.
It's partly for safety reasons, and to reduce noise from the mains supply.
They don't seem to be very common.

Once frozen, just a sharp rap on the kitchen counter/workbench will open
them. The cells are 2/3 AA cells, oddball size.. but readily available.

Seriously, there will be quite a lot of work in doing this. If you think
(for instance), of a small 8 character display, then for even simple 'seven
segment' displays, you will need to interwire the 56 control connections,
and the eight power lines, then have a character select (3-8 line decoder),
plus the individual segment selects (giving ten control wired), which you
then feed from the receiving circuit.
Much simpler (and cheaper!), to use a 'smart' display that has all the
electronics built in. Typical LCD examples are at:
http://www.crystalfontz.com/products/index-ser.html
LED versions exist as well, but nowadays the LCD versions (because of the
numbers involved), tend to be cheaper.

Best Wishes

Great ! Thanks for the good news. I was a bit worried about having to cut it... not so much as my fingers being in danger but more of destroying the casing :-)

I'm not clear here on just what you mean by "display". If you
just want to put raw data on a screen, byte by byte as it comes
from the equipment, that is one thing. If you want to show what
that data is in some kind of an orderly fashion, such as combine
multibyte binary integers into a single decimal number or put
numbers into specific columns, things get significantly complex.

>Looking at things....I think I need to use a UART 16550. Which, correct me
>if I'm wrong, converts rs232 to TTL....then I'm guessing I could put that in
>to a buffer/register/sequencer....basically store the info (how would I
>step/clock this in).
>Then I could take the byte word and parallel output it to display drivers
>w/buffers and display the data until things are updated again.

Others have pointed out the additional hardware required to
accomplish the minimal functionality, and a couple answers have
hinted or outright suggested that a microprocessor and custom
software are required. I don't think that requirement was made
clear enough.

To do anything other than just display raw data byte by byte as
it comes in scrolling from one side of an LCD screen to the
other, you need a microprocessor. One (good) suggestion (if you
have experience or want to get some in programming embedded
devices) is a low cost microprocessor evaluation board. Just be
aware that the complexity involved, if you have no experience at
that level with hardware or software development, is *huge*.

On the other hand, there _are_ hardware devices available which
can _easily_ be adapted to do whatever level of complexity you
want. It might need only one, or it might require two of them
them.

The first item needed is an older (read that as inexpensive) model of laptop! Even the oldest and least useful ones are capable of doing what you need.

The second item may or may not be necessary, depending on what you will settle for in a display. If the screen on the laptop will not suit your needs (it doesn't "panel mount" very well!), you can get an LCD display that the laptop can drive through its parallel port (if the laptop has two serial ports, a serial port display could be used instead, but many laptops only have a single serial port and that will be needed for connection the logging equipment). Others mentioned Crystalfontz LCD displays, and I would also recommend them. They have serial and parellel devices, and they have both simple ascii text displays and graphics displays. See <http://www.crystalfontz.com>.

The benefits of using an old laptop are that you can use whatever OS you are familiar with (Linux is *highly* recommended), and whatever programming environement you either know or are willing to learn (the whole thing can be done with shell scripts if you want, but could also be developed with almost any compiled language). A little thought might lead to other useful things that can be done, such as log reports. The little laptop can save log data for some period of time and then summarize it and produce reports that include almost any kind of analysis you might find useful.

Hi. Just wondering if anyone out there has changed the original Drake RX 1st IF filter and therefore has one available. Am musing over the idea of whether to use this filter in my RX.

If you have the a filter perhaps you could just drop me a post, then I can know if I can get hold of this filter. Please indicate what you might be wanting for it (hopefully cheap) :c).

My email:

news_email@REMOVEntlworld.com

Please remove "REMOVE".

Anyone have the specs for this filter? I know it's about 8 Khz bandwidth. I don't know terminating impedances.

TIA. Rich.

That filter is generally thought to be the biggest impediment
to the stock R4C being a good receiver. I would assume it was
a marketing decision, intended to make it more attractive by
lowering the price.

If you are not going to market your receiver, you probably don't
want to use that particular filter!

Instead, either watch eBay for one of the replacement filters,
or you might look into some of the AM filters for other receivers.

A quick search in eBay came up with current examples:

6 kHz / 5.645 mHz for Drake R4C
6 kHz / 9.010 mHz for ICOM
6 kHz / 3.180 mHz for Yaesu FT-101

A search of past auctions gives an idea of prices:

6 kHz / 5.645 mHz for Drake TR-7 $ 90.00
6 kHz / 5.645 mHz for Drake TR-7 87.00
6 kHz / 5.645 mHz for Drake TR-7 84.99
6 kHz / 5.645 mHz for Drake R4C 111.05
6 kHz / 5.645 mHz for Drake R4C 102.50
6 kHz / 8.830 mHz for Kenwood TS-430S 62.00
6 kHz / 8.830 mHz for Kenwood TS-430S 65.00

A google search came up with other examples:

8 kHz / 5.645 mHz for Drake TR-7

Plus of course there are the commonly available 6 kHz and 8 kHz
replacement filters for the R4C available for about $105 each
from INRAD.

And you might want to consider more than one filter and
switching between them. Both the 8 kHz and 6 kHz filters are
wider than necessary for SSB or CW and using switchable narrower
filters is probably a *much* preferable system from a
performance point of view. The only benefits to using the
wide filter early in the IF chain are 1) lower cost compared to
switching filters, 2) transient response for the Noise Blanker,

and 3) passband tuning of the entire second filter bandwidth.
If you don't need 2 or 3, the cost of switching between narrower
filters is probably worth the performance gain for a one time
only receiver project.

If you go with narrow filters, Ten-Tec uses filters at 9001.5
and 6298.5 kHz, Heathkit used HF filters, and I suppose there
are many many others.. INRAD, for example, sells a 2.8 kHz
filters that could be followed by almost any of the common
narrower (2.4, 2.3, 2.1, 1.8 etc.) filters. For CW a 600 Hz
filter can be used in front of a 600 Hz filter, or use 500/400,
400/300, or 300/250 combinations depending on what you can find.

Most of the INRAD filters have information available on them
at <http://www.qth.com/INRAD/>, and they list the frequencies
of various replacement filters which can be used sometimes to
identify less than well described used filters found for sale
in other places.

>If you have the a filter perhaps you could just drop me a post,
>then I can know if I can get hold of this filter. Please
>indicate what you might be wanting for it (hopefully cheap) :c).

With filters though, you are going to get what you pay for. If
it will do you well enough, INRAD has $24 filters too. :-)

I spent about $160 for the Yaesu 50 line, that is FL50B, FR50B, FV50B. It is a budget system really, but quite good. A beginners set. However, I'm trying to spend not very much at all improving 2nd mixer cross mod as well as improving the main selectivity (acheived at 455 Khz, 2nd IF). Heck I only paid $160 for the entire set-up! :c)

I've thought the filter to help stop the 2nd mixer from cross modulation needs to be 8 Khz wide. Such a filter will pass SSB/CW/AM, the real bandpass shaping takng place at the 2nd IF. But, actually, maybe I could go with a 6 Khz filter. For some reason the filter to "protect" mixer cross mod in the Drake RX's is 8khz wide, and I've taken my cue from this fact.

I think using a wide filter in the 1st IF would allow for passband tuning as you mention below. And I was thinking about arranging for passband tuning. I was hoping to have a good SSB and a CW filter in the 2nd IF.

The Drake filter would improve things, maybe I could get one really cheap, but would it do the job. That I don't know. Bit of a risk maybe, but if I could get one cheap maybe it's worth the risk.

Might actually be best making my own filter, but will look at "store bought" for a while.

Yes, I've been doing some research and I see the INRAD filters.
I'm busy now compiling a list of filters.

Thanks for the info on prices. I'll keep searching Ebay and see
what comes up and for what price it sells for.

If you just want to free up the laptop,
I've got a few unused Wyse WY520A ANSI terminals with unused
keyboards that I'm selling cheap.
It's an excellent terminal and I use one for console on my
unix boxes and another in the shop.
$99 includes shiping in 48 contiguous states.

Emulation mode support:
DEC
VT52 VT-52
VT100 VT-100
VT300 VT-300
VT400 VT-400
DEC-PCTerm
Wyse
WY85 WY-85
WY60 WY-60
Wyse-PCTerm pcterm
Unix console

I have a few on ebay from time to time as well if that's your preferred
venue.
http://cgi6.ebay.com/ws/eBayISAPI.dll?ViewSellersOtherItems&userid=bob%40atl.org

here is a pix at wyse with some description.
the -A is amber.

Source record: 36583
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I don't think I've seen anyone here mention the differences in charging requirements for NiCd and NiMH batteries. The chief difference is that NiCds can tolerate relatively long periods of overcharge, provided that the current is limited to about C/10 (e.g., 80 mA for an 800 mAh cell). While it's not good practice to leave them charging indefinitely, they aren't appreciably harmed by overcharge for fairly long periods. This makes NiCd cells convenient for appliances like, say, a battery operated vacuum cleaner, where a very simple and inexpensive charger can be plugged in for extended periods without worry about the battery's state of charge.

NiMH cells don't have this tolerance. Overcharging NiMH cells shortens their life considerably. In my one encounter with engineers from a manufacturer, the exact amount of life reduction wasn't clear -- apparently it depends a lot on the overcharge regimen. But all manufacturers of NiMH cells specifically recommend against overcharging them. If your rig comes with a simple-minded charger with no overcharge control, you're likely to see shortened battery life if you consistently allow the batteries to overcharge. Ideally, you should use a modern charger which detects when the battery reaches full charge, then terminates or drops back to a very low trickle charge rate (C/30 to C/50). Many brands and varieties are available now -- the ones made by Maha can accommodate the varying number of cells you'll find in HT battery packs, and I'm sure others have this capability.

My own experience with self discharge seems to agree with what the manufacturers say -- it's approximately the same as for NiCds. You can find good detailed information at the manufacturers' web sites.

Oh, one other difference is that in general, NiCds retain their capacity better than NiMHs at extremely high discharge rates. This would probably include the current consumed by an HT when transmitting at maximum power. However, people I've talked to who've used NiMH batteries in an HT tell me that the increased nominal capacity of the NiMH cells more than makes up the difference. Even if you might not get quite a proportional advantage when transmitting, you still come out ahead. And you should get the full capacity difference advantage when receiving, which is where most HTs spend most of their time.

It's easy to measure capacitance, not so easy to determine if the
capacitor works as rated because the C Value is one one part of the
picture.

But a good LCR meter should get you something practical down to 2 or 3 pf.
I have a Sencore LC-102 that does really well.

>good argument since the actual tuning of nearly all AATs, analog or digital,
>is broad enough that fine resolution is not "seen" by any antenna tuner.
>....[snip]....

For some 20 years or so my "standard" homebrew antenna tuner (even when
operating mobile) has consisted of one variable capacitor, an inductor,
and two alligator clips (^ represents the alligator clips):

```
INPUT -----X-----LLLLLLLLLLLL
^ ^
| +---Y-------
C to
| antenna
GROUND------------+------------------
```

My home antennas are usually wide-band enough that I can connect the
alligator clips to every OTHER turn, but my mobile antennas are so
narrow that I could not get acceptable SWR connecting to EVERY turn,
so I added small variable capacitors at points X and Y to essentially
give an "infinite" number of turns. The resulting tuner makes the
cab of my pick-up look a little like a grade-B movie, but the AT works
like a charm, and I can usually do small QSY's by tweaking only one or
two knobs.

OK, now I've got a better idea what you are doing!

I did a web search looking for a manual for the receiver, and
didn't find anything. Do you know of an online description or
manual that gives details on the IF and mixer schemes?

>I've thought the filter to help stop the 2nd mixer from cross
>modulation needs to be 8 Khz wide. Such a filter will pass
>SSB/CW/AM, the real bandpass shaping takng place at the 2nd IF.
>But, actually, maybe I could go with a 6 Khz filter. For some
>reason the filter to "protect" mixer cross mod in the Drake RX's
>is 8khz wide, and I've taken my cue from this fact.

In the Drake design the 1st IF filter has to be at least twice
as wide as the widest 2nd IF filter because there is only one
1st IF filter and it has to pass _both_ sidebands, only one of
which is selected by the 2nd IF filter, but since either of them
could be, they both have to be there. The actual width has to
be a little wider than that because, or at least I think it is
because, the noise blanker's gate is after the filter instead of
before it.

Hence, you don't necessarily have the same design criteria that
Drake did (though it is entirely possible that in fact you will
end up with the same requirements).

>I think using a wide filter in the 1st IF would allow for
>passband tuning as you mention below. And I was thinking about
>arranging for passband tuning. I was hoping to have a good SSB
>and a CW filter in the 2nd IF.

But you also (as is obvious from the commonly derogatory
comments about the original Drake filter) want to have
selectivity as early as possible. The difference may or may not
affect you though. For example, sitting here at the top of the
world I don't exactly have to pick signals out of a crowded

band. I hear more auroral buzz than I do QRM from the one other ham in town that operates HF. Maybe the tighter specs on a roofing filter rarely do me any good at all! :-)

But for someone near an urban center (particularly if they are "smart" and found a great location at the highest elevation around) that extra 20 to 40 dB of floor on a good filter will be the difference between ability to get into DX pileups or operate contests, or not.

>The Drake filter would improve things, maybe I could get one
>really cheap, but would it do the job. That I don't know. Bit
>of a risk maybe, but if I could get one cheap maybe it's worth
>the risk.

One advantage to doing it that way is the low expense of testing your theory... and if it works but needs a better filter _then_ you can spend the money on a drop in replacement. Anything else you do won't be a drop in replacement so much as a total (ouch) redesign...

>Might actually be best making my own filter, but will look at
>"store bought" for a while.

It's one of those "variables", that goes into the entire juggling act. :-) There are tradeoffs...

>Thanks for the info on prices. I'll keep searching Ebay and see
>what comes up and for what price it sells for.

Hmmm... I don't see very many "cheap" filters on eBay, or anywhere else. They all seem to go for premium rates. Buying two filters would more than double your investment! But that might be just the way to go.

Here are some thoughts:

If you don't need AM, you don't need anything wider than just more than twice your SSB filter bandwidth.

If you don't use the same passband tuning design that Drake did, you probably don't need a 1st IF filter to handle two sidebands. I don't find the passband tuning to be very useful for SSB, but for RTTY and CW it is essential. Which suggests that perhaps a 3.0 kHz 1st IF filter would be just fine, even though it would provide only slight adjustment of the passband on SSB. (Hmmm... maybe I should try that myself!)

Also, you can set up a passband tuning system that uses only two filters one at the 1st IF and one in the 2nd IF, that are offsetting as the passband is tuned, thus giving you variable bandwidth with only two filters. I previously posted a description of the most versatile way that could be done, but it could also be done using only the passband tuning to also

control the offset between the two filters and thus the bandwidth. (It could also be done using only 2 IF's but then the "center frequency" changes as things get tuned.)

I take it you are going to replace all of the oscillators and mixers, hence the entire frequency scheme is up for grabs as part of this project? (Find either a Collins PTO or a Drake PTO, you'll be lots happier with the stability.) I really do like the basic scheme that Drake used, but it requires some very careful attention to detail for the AGC too. In particular the RF and 1st mixer need to have good dynamic range and appropriate AGC to keep the signal levels under control before they hit the later mixer stages. (That's why they used a remote cutoff tube, the 6BA6, for the RF stage instead of a sharp cutoff that is so commonly seen.)

Actually, with the FR50B, if you only want to receive LSB on
80/40, and USB on 20/15/10 that 1st IF filter can be less than 8

Khz. You only need 8 Khz if on any particular band you want to switch sidebands and you don't alter the VFO frequency. (You don't really want to alter the VFO if a station went from USB to LSB). So, I'd say a 6Khz filter would be okay. Because of frequency translation being different for 80/40 and for 20/15/10, LSB (8/40) and USB (20.15/10) sidebands always land within the 3 Khz filter passband at 455Khz. Switching sidebands on a particular band would call for two SSB filiters at 455 Khz, or alteration of the 2nd mixer xtal osc frequency. I intend to alter the 2nd mixer xtal osc to cater for CW. To put the CW carrier on 455 Khz, rather than just off the centre frequency as with SSB.

What I was thinking is this:

Assuming that VFO is not changed when transmiting station goes from SSB to CW:

Have a 1st IF with BW say anything from 4 to 8 Khz. Wider bandwidth allows for greater passband tuning. (Probably only need about 5 Khz with the FR50B if not wanting to change sidebands on a particlar band).

Use a 2.5 Khz SSB filter centered on 455 Khz and CW filter centered on 455 Khz. Have 2nd mixer be a VXO with varicap that can be switched in, or with potentiometer marked SSB and CW. When on SSB the carrier lands off-center of 455 Khz, (say 456.5). When on CW flick switch or adjust pot. and that puts carrier on 455 Khz dead center of the CW filter. Vary pot. and that will have the effect of moving the SSB signal across passband of SSB filter.

I think the above is passband tuning.

But, the BFO signal must also track the sideband. I must figure
that out.

SSB

You have 2nd mixer VXO set to SSB. You have BFO marked SET. Here
sideband is "correctly" positioned in passband and BF0 is at the
suitable frequency. Move VXO pot. and that moves sideband across

passband. Now, just alter BF0 untill audio resolves. Don't think there is a need for automatic tracking of BFO when VXO is tuned. Could arrange for that, you just derive BFO frequency from 2nd mixer VXO.

Ought to study what Drake did.

This sounds to me like an ideal excuse to learn the PIC. It does take a little screwing your head on sideways to get into it at first, but it's pretty easy, and it's great skill to have in your toolbox.

The remarkable thing about the PIC is that it takes so little to get it cooking. You need a PIC, of course (about $6 for a 16F84), a crystal (about 90 cents), a 5 volt regulator with associated capacitors, and, of course, your LCD. (as others have pointed out, LEDs sound simple at first, but the complexity goes up very quickly). You can get LCDs really cheap from B.G. Micro, but even DigiKey has some pretty nice LCDs for around ten bucks.

of course, you also need a PIC programmer, but this is a one time investment, and you can build on pretty cheap (I once calculated $17 if you buy everything new from Radio Shack, which is about as expensive as you can make it).

Check out www.microchip.com, you can download all the needed docs and software for free, and everything else you can get from DigiKey.

Well, it was like this. They trained hundreds of search radar repair techs, and then let them loose to do their time, knowing full well that there were only 20 or so Nike Herc search radars in the whole world. So I worked on radars for almost a year at Snelling air defense site in Minneapolis, then I got shipped to Germany where I never did see another radar. That's the typical military intelligence oxymoron: I get trained for radar then get shipped to some place where my talents were unused, and you get shipped to a place with radar but with no training. Furrfu!

Maybe they didn't think very many guys would finish the course? One
of my buddies worked on the early radars and kept bragging about how
good he was at troubleshooting. He came dragging in after 9:00 one night
and said he'd spent the whole day working on dogs. I asked him to get
the schematics and give me the symptoms for the first unit, and then
asked a couple questions and told him which part was bad. In 25 minutes
I diagnosed every problem he had spent 12 hours working on and he was
pissed. He demanded to know where I learned RADAR. I laughed and told
him that RADAR was just a stripped down TV system, and a lot easier to
fix. I know I should have rubbed it in, but you get tired of some of
the guys BS after six months or so. Then I taught him some logical
troubleshooting, and he was able to find problems a lot faster.

> --
My first ay of duty at FT. Greely, AK. the station manager asked when
I graduated from Ft. Monmoth. When I told him I had been awarded my MOS
as a civilian acquired skill he grunted and told me "No civilian knows a
damn thing about electronics!" It was all I could do to keep from
laughing in his face. The TV sataion could barely get on the air and I
was told not to do anything to the equipment, but being me, I

justcouldn't ignore the challange of a piece of defective equipment. A month later I had repaired everything, and the only problem we had was film breaking, or a studio light vblowing during the live newscast.

I spent my whole time in the service working on electronics, but the only training I got was how to field strip and clean the M-16 rifle while laying in wet sawdust. Can you believe that they drafted me, gave me no training, gave me a job where you worked 40 hours in two days, then they complained that I wasn't "GI". Geeze! "GI" was enlisted, but I was drafted so I was classed "US". As Bugs Bunny would say, "What a bunch of marons!"

I worked at a radio and TV station as a broadcast engineer, did CATV work, including the installation of the first emergency alert system that took control of 17 CATV systems around the base at the flip of a switch so the base could alert people to a callup, disaster, or a war. It was so primative that we had to use dedicated telephone pairs to switch custom relays built by Winchester Electronics for the project. Of course, the civilian CATV company that served the day rooms objected, but they were reminded of the contract with the Army that they could over ride local programing in a declared emergency. Of course, I got one of those bright red flip up switch covers and used a lead seal so no one could play with it.

The TV stations was a real trip. B&W, mostly tube, and a few RTL ICs in the Grass Valley dual Sync generator system. No video tape, just 16mm film and 35mm slides. Everything was depot level maintaince, but I fixed it anyway.

WTB shaft adapters, both 1/4" and 3/8", all metal, with two set screws each side.

Need 3/8" shaft inside to 1/4" solid shaft outside; Need 3/8" shaft inside to 3/8" shaft inside;
Need 1/4" shaft inside to 1/4" shaft inside.

The adapters will probably be no longer than 1.5" overall.

Paul, K6PY

a local flea market would be better... of course at most of those you find junk like this for $1 or less in a box of other stuff. must be 12ga gold wire to sell for $14.95!

I have used the LCD+ from NetMedia (www.basicx.com) -- it has a 4X20 LCD, Keyboard decoder, 8-in 10 bit ADC, and 8 relay drivers (ULN2803A) -- a bit overkill for your operation, but having the LCD screen and matrix keyboard decoder on one board is a real plus for me. They cost about $59. It will take TTL levels on the Rx and Tx pins instead of RS232 (or you can use a MAX232) -- but the TTL levels make it easy to interface with PIC's and AVR's.

Maroons?

Hey, it could happen again. The draft, that is. Today young guys don't realize what it was like back then. I stood in line at the processing center, and some sergeant came down the line counting, and stopped and said, "Okay, all you guys, go over there; you're Marines. The rest of you go over there, you're Army." So a guy could get drafted into the Marines, which surprises some.

--
----------------(from OED Mini-Dictionary)----------------
PUNCTUATION - Apostrophe
Incorrect uses: (i) the apostrophe must not be used with a plural where there is no possessive sense, as in ~tea's are served here~; (ii) there is no such word as ~her's, our's, their's, your's~.

Confusions: it's = it is or it has (not 'belonging to it'); correct uses are ~it's here~ (= it is here); ~it's gone~ (= it has gone); but ~the dog wagged its tail~ (no apostrophe).

When I went to register for the draft they wanted to know where I worked and what I did, then they gave me the usual physical. Then they said that I had a hearing problem at some frequencies, bad feet, and that I was almost legally blind but I would be drafted because of my electronics background. Basic was hell because of my feet and legs just wouldn't take the long marches but the drill instructors were shocked by how much I could pick up by myself. I told them I was able to load almost any of the old tube type color TV sets by myself as long as I didn't have to bend over. Have you ever carried a 25" color console up a flight of stairs by yourself? I used to be able to. I could lift and hold a 4'*12' sheet of drywall with one hand and drive the nails in with the other. Today, I can only lift a few pounds, and half of my left hand is numb all the time. Life can be a true challenge at times. :)

|
|Nonsense. The Q of powdered-iron toroids using a mix appropriate to
|the frequency can easily exceed that of carelessly designed air core
|inductors.
|
||
||Certain materials have sufficiently low loss, but they tend to get
||expensive.
|
|Which is it: the loss is excessive or they're too expensive?

In my junk email box, mixed in with the ones promising the secrets to
increasing my penis size and refinancing the debts that I don't have,
was one from someone who doesn't have the fortitude to post his
comments here. I won't reveal his identity or quote the whole email
in respect to his obvious desire to not be embarrassed. I might point
out that he doesn't appear to actually have a ham license, so maybe
that's why he doesn't want to venture into an amateur radio group.

His first sentence reads:

"You're commenting on a reply, without
referencing the original question."

One should note that I quoted in its entirety the post to which I
replied. If the post that I replied to did not include the entire
thread, that's not my problem. Furthermore, if every post included
every comment that went before, Usenet would probably go into
denial-of-service mode.

There was more castigation about my tone and the "fact" that my post
was "off-topic."

Let's examine this.

A blanket statement was made that all RF power inductors have air cores. That is absolutely untrue and I offered a case in rebuttal, which other have confirmed in later comments.

The post to which I replied then appears to imply that there *are* core materials equal to or better than air, which contradicts the earlier statement.

I pointed out the contradiction.

My adoring fan then when on to get his panties in a bunch about the fact that I brought up "torroids", as he misspells it, and that since the topic of mobile antennas is in play (but nowhere to be seen in the post that I replied to) I should confine my comments to that.

Okay. I will just say that *I* know how to vary the inductance (without switching taps) of a coil wound on a core of toroidal shape. Using this principle, I could use a toroidal inductor at the base of a mobile whip and vary its inductance such to resonate the whip.

<beerbarrel@cox.net> writes:

>Anybody ever dealt with the cheap LCR meters versus the older genrad
>type bridges? If so, how do they compare? Can you get good accurate
>readings on the digital meters? Even on very low readings such as 4 or
>5 picofarads?

Yes and no. :-)

For a capacitance measurement accurate to a few picoFarads with a
"simple" instrument, you can expect manufacturer's stated accuracy
with a capacitance meter (portable, hand-held) with a 200 pFd range.
With the common "3 1/2 digit" display, it can resolve 0.1 pFd.

A typical accuracy for a 200 pFd range is +/- 0.5 pFd...provided the
zeroing is done properly and hands, other objects don't interfere with
the reading.

All anyone can do is to believe the manufacturer's statements on meter
accuracies. Read those in detail...add up the (usually) separate
stated accuracies for the worst accuracy overall.

One way to check small LCR meters on capacitance is to "substitute
compare" any small capacitor with the capacitance (tuning) control on
Q meters. Those capacity scales are quite accurate (again, read the
manufacturer's stated accuracy values). With any resonating coil in
place and capacitance control set to a convenient higher value, add
the fixed comparison capacitor on the Q Meter. Back off the Q Meter's
capacity control until you get resonance. The fixed comparison cap's
value is the difference of the Q Meter capacitance control readings.

Jeremy,
Filter caps were much lower values in 1940 than they are now. Instead of using 16 mf caps, use a 50 and a 200. You will not need a high reactance choke. You could even substitute a 1-2K resistor. Put you money into a power transformer and 6 volt tubes instead. That thing looks like a deathtrap!

My first exposure to it was 20 years ago in Haywards Introduction to RF design. Pg 216. I built one tested by G3SBI and using a VMP-4 at 28 volts @ 0.7 Amps that measured +56 dBm Ip3. Have 2-3 of them around as shop amplifiers. Problem with it as a post mixer amplifier, was that if hit with appreciable RF, it could put out 7-8 watts and fry any subsequent filter. We have reduced our sights on the holy grail and settled for a quad set of J-310's as post mixer amplifiers biased to about 80-90 mA. Those will do +26 dBm input Ip3 and still flatten out at about +10 dBm or so if accidently driven hard. BIG advantage is unbelievably low Noise figure. Have measured several at under 1.3 dB

The source impedance MUST be kept very low if to be broadbanded. In that respect, the VMP-4 with it's 12 bonding wires from source to bridge did very much better than MaCom's DU20 with only two. Excellent writeups by Pat Hawker in TT going back at least 5-6 years

I have never found it in SSD, despite having 3 copies. (One shop, one shack and one in the "reading room"). It is described and explained in Haywards new Son of SSD, "Experimental methods in RF Design". Also as previously mentioned in IRFD, originally published in hard back in 1982.

Trasks Augmented amplifier, and augmented mixer are quite complex, and in the case of the mixer at least, don't bring anything to the table that a good symmetrical FST 3125 can't better. I've never built his amplifier, nor found the measured specs on it.

2417. Another dumb question!

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-29 23:17:15 UTC
From: Tracy Fort <beerbarrel@cox.net>
Message-ID: <3cac8vctqnus5gkbf3a4gl8jrkacfv053i@4ax.com>
Source record: 36520

Here goes...

Picked up a 12v power supply for my ham radio that has a 25 amp
output...

When I put the volt meter on the power supply I have an output of 13.8
volts. I can adjust the pot inside and get it down to about 12.5
volts...no problems

but when I hook up the radio to the supply with the voltmeter still
connected in parrallel to the radio the voltale goes up to over 19
volts...is this normal operation or is something amiss..I don't want
to destroy my radio...

Any help?

thanks,
Tracy

Something is not right. I would try hooking a headlight bulb to the supply to see if that also sees excess voltage. It sounds like the rectifier filter capacitor is open, and you are adjusting an average voltage that includes both the regulated peaks, and the low voltage between them. Then, when you connect a radio, its supply input capacitors are charging up to the peaks, and holding up during the dips. A headlight will not do this, but a headlight in parallel with a big capacitor will.

It is also possible that the regulator is going nuts when this load is connected, and changing the effective output. An oscilloscope would quickly tell you if either of these was going on.

Tracy..

What's the input resistance of the voltmeter?

To tell you the truth, I don't know. I can tell you it's a simpson model 467 high impedence meter. I now know that the pot to make minor voltages was open. I don't know what the value is but I subbed in a 0-30k pot and now the voltage bounces between 13 and 16 volts when the radio is hooked up. It is fairly steady at 12.8 when the radio is not hooked up. This power supply does not use a standard rectifier bridge. It has 2 big diodes with a small filter cap between them. To me, it seems as if some ac voltage is leaking through. Of course, I'm along way from an expert....

Tracy,
Is this power supply a "battery charger"? Battery chargers generally put out unrectified, pulsating direct current. Your voltmeter will display the average voltage. When you put a capacitor across it, the capacacitor fills in the gaps in the supply output and you will read a nearly peak voltage, about 1/3 higher. Your radio would have capacitors at the power input.

Yes...It is a csine power verter used in the rv industry. It has 5
connection points with fuses under the front cover. One of these is
marked for a radio. I really bought the thing to make a p/s. It had a
18v 25a transformer that seemed very usable to me. When I got it, I
thought that I could use it the way it was. Is the thing usable or
will I need to go back to my original plan?

Tracy,
Try placing a filter capacitor across the output and see if the voltage
jumps up. That would indicate an unfiltered output.
How much current does your radio use? Is it a receiver? Transceiver?

I did that..I used a 1.6uf and the voltage went up about 1.5
volts...That explains the lack of a rectifier bridge. It has two
diodes with a cap across them. The output looks to me like it has AC
in it. The meter reading is steady but it has that graphical bar under
the readout that bounces up and down...

I will be using the supply with a hf transceiver that has a 100 watt
output. I thought that I might build another circuit board and use the
existing transformer. It is in a pretty neat housing that could be
reused...

Actually NOT a good idea to use a battery charger type supply
to run a tranceiver. You want a well filtered, regulated supply with
crowbar over voltage protection. You could ADD this circuitry to
the output of a power supply lacking this if you already have
a supply with a good transformer and rectifier.

Man trash this thing before you blow your rig. At the very least, buy
an Astron and be done with it.

I'm even in the process of converting an Astron to a battery charger
for my RV just to get rid of the switching noise from the POS built-in
charger.

I don't sell Astron or have any interest in them. They just seem to
offer the most bang for the buck.

Tracy,
A full wave rectifier from a center tapped transformer would be two diodes with a capacitor across them...
As John Popelish suggested: the cap may be open, or possibly it is made to be used with a battery at the output.
For RV use, it may be a battery charger...The voltage would go high to start, and drop down to close to 12 volts when the battery is charged.
Possibly it should be used with a battery rather than as a battery substitute. This is just a guess. I cannot find "c sine power verter" on the web.
You really need more information before you plug your radio into it again.

1.6uF isn't nearly enough capacitance, even for running the set on receive.
If I were you I'd junk it, unless you actually like building stuff. Nowadays
you cannot save any money by building your own supply, the only reasons for
doing so are because you like it, or because you have a unique requirement.

Not to be argumentative, but I'm wondering if the dual Sync Generator system you're referring to wasn't made by Telemation...not GVG ? I don't recall any RTL parts in early Grass Valley products, but I do recall an old 1RU high Telemation sync generator with beige/tan front panel and built-in changeover relays. Two of the boxes would've comprised a "dual sync generator system". Not sure if it used RTL or not (for some reason, I think it was TTL but it's been a long time ago)......

So the csine power verter is homebrew?
|
|The cap was just for a test.

You need tens of thousands of uF for a start. Then you need a 723 or similar regulator chip and support electronics, a predriver transisor and probably four power transistors for series pass elements. An SCR crowbar would be a good idea too since I think you've probably used up your allotment of good luck in not having already blown up your radio.

No...my original idea was to rob the transformer out of the power converter and construct a power supply. After I obtained the power supply, I though I might be able to use it as is.

Like I said, I used the cap to see if the voltage stabilized any. It did. I wasn't trying to make the supply usable with the radio.

The radio I hooked up was an old 2meter beater that I had lying aroud. It was not the rig that I plan on using with the supply. If it burnt it up it was no big deal.

The converter had 5 outputs, one of which goes through a circuit board and is supposed to be a filtered output for a radio. That was why I though it might work. Something is evidently wrong with the board. Either way, It does contain a very usable 18v 25a transformer, a nice case, and a large heatsink. I think with a few dollars I can construct a nice power supply. In addition, I might be able to learn something. That's why I was posting this in the homebrew section. I guess I get more satisfaction out of building that buying.

anyway...thats my story and I'm sticking to it...

There may not be a thing wrong with it. If you put a battery on
it the various output will stablize and it will filter out noise
and AC ripple. A battery is much like a really good capacitor,
as far as filtering goes, and much like a poor zener diode as
far as voltage regulation.

The only question is whether this charger is designed only to
charge a battery or if it can also maintain a float voltage when
the battery is fully charged. If it can maintain a float
voltage you've got a nice setup for emergency operation when the
AC power fails.

Sounds good to me, but I'd first take a look at figuring out
exactly what it was meant to do in the first place, and see if
that isn't more interesting that using the parts for something
else.

Could those be Silicon Controlled Rectifiers (SCR) instead of regular diodes? That would give an irregular waveform yet would be OK for running resistive type loads in an RV. That's what was in my trailer.

In 1999 I had problems with overvoltage on the power converter in my camper trailer and the folks at BR Wholesale in Marshall, MI were able to help me. They explained the circuit to me. Give them a call at 1-800-848-0934. Won't hurt and might help.

If you do decide to strip it out, there is an excellent 723 based design in
the ARRL handbook.

I built a 12v 100A version of the RF proof 24V supply. That circuit was not
in the 2002 edition, so you might want to trawl through some old issues too.

Good luck

Arcade Electronics in Alexandria has some parts. I get most of my
stuff via the Internet from DigiKey and Mouser these days. Place the
order on the Internet, give them your Visa or MC number and it'll be
setting on your doorstep via UPS in three or four days. Much easier
than fighting the DC area traffic.

2447. Using an old radio's variable capacitor

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-31 02:37:15 UTC
From: Yap <meihoon@pl.jaring.my>
Message-ID: <b689kr$4g5$1@news4.jaring.my>
Source record: 36449

Hi all,

Recently got an old variable capacitor off a discarded walkman.
It has 6 terminals, 1 in each corner and 2 flat ones on the side.

I now know it has sections for AM and FM in the same casing.

The question is : is it possible to hook it up so that I get
a shortwave antenna tuning capacitor?

I'm worried that if I use the AM section, it won't go down low
enough to receive the shortwave frequencies.

--> Chops

> for sale, but the chain has now evolved....

<snip>

My personal favorite is the term "degenerated." "Devolved" also
works.

Anyway... The "quality" (or lack thereof) of many of the parts that
RS still stocks is enough to turn me away.

There are three sources I currently use; Mouser, Allied, and Digi-
Key. Between the lot of them, it's a very rare item that I can't locate.

> So where can I go these days? I'd like to browse through the parts myself,
> and I'm reluctant to mail order stuff I haven't seen and touched.

No need to fear, as long as you order from a reputable dealer. The
parts I've gotten from all three sources are, as near as I can tell, top-
rate.

> it was TTL but it's been a long time ago)......

It was built in 1972 or 1973 and was two rack units high with two plug
in sync generator modules, two plug in power supply modules, and a plug
in changeover module. It used RTL ICs in TO-5 cans and had +12, -12, and
+3.6 volt power supplies. It was mostly discrete parts but it used RTL
to divide the crystal down to 15750 and 60 HZ then it used analog
circuits to set pulse widths. By today's standards it was a piece of
crap, but it beat the hell out of the vacuum tube sync generator it
replaced. It was 1/6 the size and only drew about 40 watts, instead of
200 watts. The Video and Pulse Distribution Amps were Grass Valley as
well, and were completely discrete parts. The power supplies were the
same as the ones for the Sync generators, minus the 3.6 volt supplies.

Don't use this unit to power your radio, it's protection circuits are some
what suspect.
By all means use the transformer for a home brew PSU (it sounds ideal).
If you want a good circuit for a PSU (up to 40 amps) with FULL protection
let me know your address off list and I will send you it (I have used this
design for the last fifteen years or so on
lots of supplies I have build for other folk and not one person has had a
problem..cheers,
Ken, G4KIR.

2451. Collins/Rockwell filters

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-31 09:23:55 UTC
From: Richard <nearlynews_email@ntlworld.com>
Message-ID: <b691bv$28m5d$1@ID-150848.news.dfncis.de>
Source record: 36453

It seems, but I don't really know, that in the main RX's and TX's use one SSB filter, the carrier frequency being moved over from one side of the filter passband to the other. The actual center frequency of the filter is 455 Khz (for 455 Khz filters, that is).

It seems therefore that using two filters is less common. That is a seperate filter for each sideband. Here, the filter's stated frequency is not the actual center frequency, but the carrier frequency. So, for the Collins 455 Khz LSB filters, the actual center frequency is above 455 Hhz, USB filter, center frequency is lower.

Now Collins/Rockwell make symmetrical filters. What are these for? And, are the sideband filters not symmetrical in their passband? TIA. Rich.

Morning!

I am looking for info on building xtal controlled CW transmitters for 50, 144, 222, & 432 Mhz.

They will be used as CW beacons that runs continuously atop a mtn here in DM09.

The ideal power level would be 5 to 10 watts. Any help out there?

Thanks!

> enough to receive the shortwave frequencies.

"Shortwave antenna tuning" is a pretty nebulous description of what you want to do. What sort of antenna? What sort of tuning--what do you want the tuner to do and why? What frequency range? Do you have a circuit configuration in mind? And I assume this is for receiving, or VERY low power transmitting.

Tuning to me implies resonating. What inductance do you want to resonate? Inductance in the antenna's impedance, or in a coil in some sort of preselector? If it's the latter, you should be able to wind a coil (or coils) which will resonate with the capacitor you have. Then it's a problem of using that in a circuit which accomplishes the goal you have in mind. You should first find out what the capacitance range of each section is, though. I suppose there are probably four capacitor sections, and likely each has a different range.

Cheers,
Tom

Good evening! (in Europe, of course)

Recently I have caught an idea of building an automatic antena tuner. I have also some questions about this. The first is about the idea how it should work. Do I measure the amplitude at the output and set the capacitors and inductors to obtain maximum amplitude? In some design I have noticed there were two variable capacitors and switched inductors. It makes three variable devices altogether, so what is the algorithm of setting them?

Thanks in advance!

It's not, or at least this isn't evidence of it. It's programmed in the
"alter only the bits that need altering" method.

Now if you found win3.11 in 9x, or 9x in NT, that'd be evidence of c/p
programming.

Given that it is really a battery charger, do you have a 12V lead acid battery
across its output?

The battery will act as a reasonable "regulator" and probably allow you to
use the charger as it is.

2460. Where to buy semirigid coax

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-03-31 19:58:11 UTC
From: k7itm@aol.com
Message-ID: <3200347.0303311158.acc94c5@posting.google.com>
Source record: 36463

Hi all,

Anyone have pointers on where to buy small quantities of small
semirigid coax at a reasonable price?

Cheers,
Tom

2461. make money fast and easy!!!

service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list.

~~~>HERE ARE 4 EASY STEPS TO GET STARTED<~~~

STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (Please make sure that the bill wouldn't be noticed in the envelope to prevent thievery). Send out US $ DOLLAR, so it would be more acceptable.

STEP 2: Next, place one paper in each of the 6 envelopes and seal them properly. You should now have 6 sealed envelopes, each with a piece of paper stating the phrase, "PLEASE PUT ME ON YOUR MAILING LIST.", your name and address, and a $1.00 bill.

What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting for a legitimate service and you are paying for it! Like most of us, I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal!

Mail the 6 envelopes to the following addresses below:

#1)B. Hooper ; 3 Warringah Gve.
Petrie, QLD, Australia 4502

#2)Matthew Speight ; 6 Charnwood Ave.
Belfast , N. Ireland : BT15 5DH

#3)Ahmad Mujeeb ; 307-14 15 st, NW,
Charlottesville, VA, USA, 22903

#4)Rostum Hernandez ; #2 Jericho St.,
Victoriaville Subd. ,Antipolo City,
Phillippine, 1870

#5)R.Pena ; 1962 46St. S.W.,
Naples , FL., USA, 34116

#6)sara siemon
9245 lower valley pike
new carlisle,oh 45344

STEP 3: Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list.

STEP 4: Copy this article. Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (I think there are close to 2.4million groups) All you
~~~

need is 200, but remember, the more you post, the more money you make! This is perfectly legal! If you have any doubts, refer to Title 18, Section 1302 and 1341, US Postal and Lottery Laws or Title 18, Section 3005 in the US code, also in the code of Federal regulations, Volume 16, Sections 255 and 436, which states; "a product or service must be exchanged for money received." The simple note in the letter, "PLEASE PUT ME ON YOUR MAILING LIST", makes it legal because you are paying for exchange of a service, (adding the purchasers name to his mailing list) for a $1.00 fee.
: Keep a copy of these steps for yourself and, whenever you need money, you can use it again, and again. PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way.

NOTE: You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.) So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of dollars in CASH!!! What an opportunity for only $6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you're in business!

~~~>DIRECTIONS FOR HOW TO POST TO NEWSGROUPS<~~

Step 1) You do not need to re-type this entire letter to do your own posting. Simply put your mouse cursor at the beginning of this letter, click and drag your cursor to the bottom of this document, right click and select 'copy' from the edit menu. This will copy the entire letter into the computer's memory.

Step 2) Open a blank 'notepad' file and place your mouse cursor at the top of the blank page. Right click and from the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name and postal address to the list.

Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to.

Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions.)You can post anywhere!!! There are tons of free bulletin boards if you just look for them!!

Step 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the "post" message button. You're done with your first one!
NOTE: Please don't SPAM or send unsolicited emails. It's completely illegal.
~~~

Send emails to all the people you know or any ways that allows you to, instead of SPAMMING.(Just a reminder).

Congratulations...THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about a minute for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O.Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.**

*Now the WHY part; Out of 200 postings, say I receive only 5 replies (a very low example). So then I made $5.00 with my name at #6 on the letter. Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each, I will bring in an additional $125.00! Now, those 125 persons turn around and post the MINIMUM 200 with my name at #3 and only receive 5 replies each, I will make an additional $626.00! OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at #2 and they each only receive 5 replies, that just made me $3,125.00!!! Those 3,125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still ONLY 5 persons per 200 newsgroups react I will receive $15,625,00! With an original investment of only $6.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is: do you realize that thousands of people all over the world are joining the internet and reading these articles everyday?, JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really works?? I think so... People have said, "what if the plan is played out and no one sends you the money? So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users, every day, with thousands of those joining the actual internet!!! REMEMBER, PLAY FAIRLY AND HONESTLY AND THIS WILL WORK FOR YOU!!!

Besides any harm caused by your wife shooting you, a lead-acid battery
gives off fumes from (and could spill) sulfuric acid, which could
damage many things in your house, including occupants. I wouldn't have
it any more inside than a garage or shed.

Think on a remote mount with just the power lead running to your shack
area.

Happy trails,

Test it first. But if it works as desired you can buy an
appropriate battery box to safely store a battery in. This is
almost identical to a UPS except you don't convert the 12 VDC to
115 VAC to use it. The battery is certainly no more danger than
the battery in a UPS powering your computer (or a battery
powering an emergency lighting unit, as another example).

Batteries are *very* good filters, which is why the unit has
such horrible filtering with no battery attached. You won't
need to add any capacitors if you put a battery on it. The
regulation will also be much better, with 12 VDC probably being
the minimum, and perhaps 14 VDC being the worst case maximum.
However, the 12 to 14 VDC varies with the charge in the battery,
so it might change over several hours (and of course could go
below 12 VDC if no charging current is present). The regulation
over a period of seconds or fractions of seconds with load
variations will be very small (fractions of a volt).

If your unit is actually designed to do that it would be a shame
to part it out just to get the transformer. Sell it to someone
that can use it, and either buy a transformer or buy a plain old
battery charger to get the transformer from it.

You've never heard of sealed batteries?

You've all seen those little boxes with emergency lights in
every store in the country? You've all seen those nice little
UPS boxes that keep your computer from crashing when the power
fails? Got a burglar alarm system? Or a fire alarm system?
They *all* use sealed lead acid batteries.

You get the idea. Even the battery in your car is unlikely to
be able to spill acid or give off fumes.

The stated center frequency of a filter is usually the actual center
of the filter unless they are stated as upper or lower side band
filters.

The situation with Collins 455 khz filters is that is the center
frequency (455) khz. The carrier is set to one edge or the other for
upper or lower side band operation. That puts the side band energy in
the center of the filter.

Yes they are symmetrical filters.

Switching the carrier from one side to the other and using the same
filter is less expensive than having two filters.

There are some schemes that allow switching side bands without moving
the carrier to the other side of the filter. Look at a schematic of
the SBE 33 or SBE 34 transceiver. It uses a single 455 khz filter and
one crystal. The crystal is set at 453?? something to put it off to
the side to generate upper side band. Then the output of the 453 khz
crystal is also fed to a multiplier stage and to a mixer that is also
fed by the output of the filter. There is an intermediate IF of around
1.8 mhz if I remember. The multiplier stage for the 453 signal is
either multiplied 3 times or 5 times? That puts the input to the mixer
either above or below the 1.8 mhz IF. That will give either upper or
lower side band out of the 1.8 mhz mixer with the same carrier

frequency.
The only thing that is needed to select side bands is to select a couple of tuned circuits in the multiplier to be tuned to either 1359 khz or to 2265 khz. Works well.

A typical car battery today will not vent fumes under the normal
circumstances that you would be using it. That vent will,
however, certainly keep it from exploding if you put it in trash
barrel and try to burn it...

The key is to look for a "maintenance free" battery. If you can't
put water into the cells, then the battery necessarily cannot let
fumes escape either (because the corrective action would be to add
water, which can't be done on sealed batteries).

That's straight out of "A Sideband Package" by George Bigler in
QST for June 1958. I have no idea if he got the scheme from elsewhere,
but this was a pretty popular homebrew rig, and I've seen other construction
articles using the same sideband selection scheme, and they attribute it
to Bigler's article.

The second IF is 2.25MHz. The carrier oscillator is doubled, then either
doubled again (to provide 1.8MHz) or tripled (to get 2.7MHz).

This setup would work better in a transmitter than a receiver.
In a transmitter, you've got a controlled situation, so if a spurious
signal is generated, you can just notch it out. Putting it in a receiver
(as Bigler suggests) means you're back to a situation where there will
be limited selectivity at the first IF, and there goes your signal
handling and image rejection specs. Of course, back when he wrote the
article, such a scheme of a few tuned circuits at the first IF was
common. Now, you'd want a crystal filter at that first IF, and
then comes the issue of getting one at a frequency where everything
lines up. It is simpler to move back to two separate injection
crystals for the conversion to the final IF, and switch between
them to provide for inversion or no inversion.

SOmeone updated the Bigler sideband selection scheme in Ham Radio magazine in the early seventies. Instead of multiplying, he used a higher frequency crystal, and divided down.

Using a charger intended to charge an automotive battery, to float a sealed battery, is likely to ruin the sealed battery for a couple of reasons. One is that the maximum charge current might exceed the rated charge current of the sealed battery. The second is that the float voltage required for long battery life will be lower than the voltage used to recharge or top up an automotive type battery. This will result in constant overcharge and a short battery life. Even if you use an automotive battery, the charger voltage is likely to be too high for sustained float operation. The result will be that the battery will vent hydrogen gas, and battery life will be very short.

There was a Wizard of Id cartoon hung on our bathroom wall for a number of years. The Wizard's unattractive (to be charitable) wife Blanch was at the hairdresser's. Blanch: "I'm going to the royal ball tonight, Pierre, and I want to be the most beautiful woman there. What do you recommend?" Pierre: "Reincarnation."

I think that's your solution. Use the transformer to build a proper supply.

"Sealed battery" does not exclude "automotive battery". What
you meant to say was that if the charger cannot be adjusted,
then it must only be used on the type and size of battery for
which it was designed.

But then that was the reason for suggesting that Tracy figure
out exactly what this device *is* designed for before tearing up
a very useful piece of equipment to make a pile of junk.

>reasons. One is that the maximum charge current might exceed the rated

Nobody has suggested floating a battery at the boost charge
rate. That is absurd.

>sustained float operation. The result will be that the battery will vent
>hydrogen gas, and battery life will be very short.

You'd best never turn your transmitter on then, because if you
allow it to draw too much current, it will vent blue smoke and
have a very short life.

Why not figure out what the device is first. Sounds like that
transmitter you should never turn on might be a good source of
transistors for the next code practice oscillator you want to
build, eh?

Don't you think a little common sense should be used instead of
ignorantly destroying things?

Those are fine, as they are designed for that sort of use. His earlier
post didn't distinguish and it seemed like he was going to use a car
battery.

You are right, I should have mentioned those as the alternative.

>You get the idea. Even the battery in your car is unlikely to

Unlikely, but if it does, sulfuric acid fumes do interesting things to
nylon and some other plastics.

>>Think on a remote mount with just the power lead running to your shack

Depends on your power needs for the radio, but the majority of
circuits in your house are rated 15 or 20 amps. You could upgrade to
12 or even 10 gauge wiring, which would work fine in many situations.

Anything like this should be done by a licensed electrician, or at
least to NEC standards.

I agree with all you've said, with the exception of the statement about never turning a transmitter on, which I didn't understand.

I assumed by the statement about the supply's use for an RV that it was probably intended for normal cyclic battery charging rather than float charging. And of course vehicle-sized sealed batteries are available, but since the ones I've seen easily cost as much as or more than a power supply, it never occurred to me that this would be a viable option. And, finally, I interpreted the suggestions about getting and using a battery, and the allusions to a UPS, as suggesting float operation. I didn't think that he would be interested in connecting the charger only occasionally and monitoring the charge.

So, given that my assumptions were apparently incorrect, I apologize.

Yes, so the Collins 455 Khz USB and LSB filters have different
center frequencies. 455 Khz refers to carrier
frequency.

This is just for the symmetrical filter, ie, *not* stated as
being a LSB or USB SSB filter. I guess this filter is for when
you move the carrier into correct position, as contrasted with
keeping the carrier at 455 Khz and swapping filters.

There is a *huge* difference between a couple volts drop when
the circuit is powered with 120 VAC, a couple volts drop when
the circuit is 12 VDC.

>73 Gary N4AST

I don't know what happened there. Concerning an automatic antenna tuner, there are various commericial units available that work quite well. They use different sensors and algorithms to make them work.

One method that I have been experimenting with involves a capacitive voltage divider, and a torroid rf current pickup to sample V and I to the antenna. Use an op-amp ratio detector to determine when the Z is 50 ohms, (or 75 or whatever), and use a phase detector to determine whether the antenna system is Inductive or Capacitive. Armed with this information, we have Z at some angle, which translates to R+-jX for the system.
If we know R and X for the antenna system, that can be plotted on a Smith Chart, and it can be shown that a re-configurable L network with a single variable inductor, and variable capacitor (with sufficient range) will match anything to anything.
The tuning strategy or algorithm can be deduced from the various steps on the Smith chart to obtain the desired match. This is one of many ways.
The small commercial device I have uses a Pi network, with a phase detector, Z detector, and a reflected power detector. Works good, algorithm is propriety.

If it has a separate supply line for a radio (as Tracy
described), it appears that this unit might well be intended to
be plugged in for continuous duty whenever AC is available. That
would require that it float the battery rather than just give it
a maximum charge. Even the vehicle's charging system floats the
battery when it is fully charged... they just figure on 5 years
of battery life rather than the 20+ years that other applications
(say a battery backup system for a repeater) might have.

>And of course vehicle-sized sealed batteries are available,
>but since the ones I've seen easily cost as much as or more than a power

I was under the impression that most vehicle batteries today are
one type or another of a sealed, maintenance free battery. I
know that I haven't put water into a car battery in so many
years that I can't remember the last time I did it. I'm not
exactly a car mechanic though, so my experience might be odd and
not really indicative. ;-)

>finally, I interpreted the suggestions about getting and using a
>battery, and the allusions to a UPS, as suggesting float operation. I
>didn't think that he would be interested in connecting the charger only

I agree with you. I'd think that plugging it in and leaving it
"forever" is probably the normal way! (I've seen some really
dead UPS batteries that have been sitting for five years that
way... :-)

>So, given that my assumptions were apparently incorrect, I apologize.

No problem. I've been putting water in telephone company
battery systems for decades (including some small earth station
equipment in the 80's that used 24 volt truck batteries no
less), so this particular stuff just kinda seems obvious to me.

On the other hand, I enjoy very much learning about a variety of
things regarding antennas, and other stuff, that I've seen you
post recently.

There's a difference between sealed and maintenance-free batteries. Maintenance-free batteries are vented and contain liquid electrolyte just like the old-fashioned non-maintenance-free types. The only difference is that something (I'm not sure what) has been done to reduce the rate of electrolyte loss. They do, however, lose electrolyte over time, and I've recovered more than one "dead" maintenance-free battery by prying off the vent covers and topping the cells up (to the bottom of the split neck) with distilled water just like we used to have to do regularly before the maintenance-free days. Maintenance-free batteries vent hydrogen gas on overcharge the same as the older types, and should only be used in a well ventilated area.

By contrast, sealed batteries are really sealed. Some at least have the electrolyte absorbed into the blotter-like separator material and don't contain liquid. These can vent, but only under abnormal conditions of overpressure. Sealed batteries of vehicle size have only recently become widely available. The few I'm aware of are several times more expensive than a typical maintenance free battery. Hams like to call these "gel cells" (which was a trade name of, as I recall, Globe). However, gelled electrolyte is very unusual these days -- virtually all the smaller batteries at least are of the "starved electrolyte" variety.

Thanks for the kind words. We all learn here.

You may want to look into the older FM comeracial rigs. Just cut off the
audio. The only problem may be the 220 band. I think there have been some
conversions of the GE Mastr ll units to the 22o band for the exciters and
you need one of the ham band type amps to go from about 200 mw to the level
you want.

Since you are trying to match an unknown impedance to some standard impedance, you will want a way to detect when the match is good enough. One way to do that is just with an SWR bridge. Then you tune until the SWR is low enough. The problem with that is that you don't have much of an idea how to start, so some automatic tuners measure not only the reflected power, but the phase as well. You can get a clue by just noting which direction the SWR goes as you start tuning, but if the SWR is high, the change may be so small as you tune one of the components that other errors dominate and fool you. The phase plus SWR lets you know the full complex reflection coefficient, and from that, the impedance you must match.

If your goals do not include significant rejection of harmonics, then your algorithm should try to keep the loaded Q low. The reason for that is that a high loaded Q implies more power lost in the tuner, assuming that the capacitors and inductor(s) have reasonably constant Q independent of their settings. That's not strictly true, and you might do a little better with an algorithm that takes account of the component Qs versus settings, but it may not be worth the effort.

The algorithm should also know when to quit trying, in case it can't tune some particular load.

Cheers,
Tom

Tom,

the antenna itself is just a loop with a variable cap connected in
series.

here's where I found it --->

http://www.creative-science.org.uk/loopant.html

It seemed pretty simple to this layman so I decided to build it.
I'm hoping to get good reception on the 49 meter band.

However, seeing as how AM tops off at about 1 MHz and I want signals
of around 6 MHz, I worry that the AM capacitor may be too large.

You have it right. However all the 455 khz Collins filters that I can
think of off hand are symmetrical filters and have the carrier offset
to one side or the other. I also can't think of any collins filters
that are not symmetrical no matter what they were made for.

Non symmetrical filters were usually crystal filters that were built
with a small number of crystals. With only 2 or 4 crystals in a filter

it is difficult to get good steep skirts on both sides of the filter. So they were often made with emphasis on one skirt for best side band suppression on that side. The other side would roll off less sharply. By using more crystals in the filter it is easier to get steep skirts on both sides of the filter.

A common filter arrangement that was used by collins was a 500 khz filter. These were usually upper or lower side band filters with the carrier at 500 khz.

Most 455 khz filters that you come across will have a center frequency of 455. These need the carrier set to one side or the other.

I love my AADE meter for the inductance function, but the capacitance function does not do so well. Checking with precision caps, mine had a 4-6% error, sometimes high sometimes low. My 2 other commercial LCR meters were under 1% on capacitance--but they were very poor on inductance (the main reason I got the AADE kit).

I don't know if this is the best way to do it, but I use it
to adjust my tuner manually: use a phase detector circuit.
Voltage and current will be in phase when the transmitter sees
a purely resistive load. There's a good description of the
circuit at
http://www.tpub.com/neets/book12/51c.htm

Look for the write up on the Foster Seely discriminator.
Don't be misled by the fact that it is used as an FM demodulator -
it works fine for determining resonance.

> In some design I have noticed there
> were two variable capacitors and switched inductors. It makes three variable
> devices altogether, so what is the algorithm of setting them?

I'm not sure, but I think those depend on a signal or voltage
level from the transmitter that corresponds to a band. That signal/
voltage could be used to set the inductor, then the phase detector
output can be used to set the capacitors. In my case, I manually
set the inductor, then watch the phase detector null meters
as I turn the caps, looking for null on the meter. My
discriminator is a surplus unit (bought it for about $9.00 from
Fair Radio) that has outputs for 2 null meters.

SB34.. Now THAT brings back memories.

I used to work at the factory, and we did indeed use a single 455 KHz mechanical filter with the mixing scheme as described to get upper/lower sideband.

Strong signal handling was not thought about very much in those days, it used germanium transistors in the IF amplifiers and a single diode as one of the mixing stages!!!

For it's time, with the bilateral amplifiers and so on it was a nice design but in terms of performance the entire concept is obsolete.

A CAREFULLY designed system can use a 455 KHz filter, usually at least a dual conversion of some sort, but a single conversion rig, with the crystal filter right after the first mixer will in most cases have better strong signal performance.

That cap probably resonates with a loopstick that may range in value from 200 to 400uH, depending on the value of the capacitor. I am not sure that your antenna has enough inductance to form a resonant circuit with that cap at 6MHz. I know that you were worried about not reaching up to that frequency range, but I think that the opposite may be true. You may need an additional series inductance in order to form a resonant circuit on the 49M band. A network analyzer (expensive), or an antenna analyzer, such as the unit that MFJ has available, should be able to show you what is going on, but I think that even that unit is right around the 200 dollar range. Don't give up on experimenting, though; that is where the real fun of the hobby is!

OK, so you want to resonate the inductance of the antenna itself with
the capacitor. You just need to make the loop small enough that its
inductance will resonate with the capacitor you have... OR ... add a
fixed capacitor in series with the one you have. (Or perhaps in
parallel with one of the FM sections.) You won't have as wide a
tuning range, but the specific band you want to hear isn't all that
wide as a percentage of its center frequency anyway, if I'm not
mistaken. You can tell when things are resonant by the sharp peak in
the tuning. Reg Edwards has some programs that should let you make a
good estimate of the loop's inductance, I believe. You should be able
to find postings from Reg in this group, and in most/all, he gives his
web site URL.

Cheers,
Tom

The 455 Khz symmetrical filter offerings have a symmetrical passband I guess. But why call them symmetrical filters. First thought is that the USB and LSB filters are assymetrical, so it's differentiating re passband shape, but you say the USB and LSB filters are symmetrical.

Not really important, but just unsure why call the 455 Khz filters, which are meant to be used where you alter the carrier position, a symmetrical filter. Maybe it's just the best term the Collins came up with to differentiate these filter from the LSB and USB filters, where the carrier stays put on 455.

Not that I am aware of, but you should be able to use
alt.binaries.schematics.electronic. This is used sometimes by
sci.electronics.design and should be acceptable since some people watch both
groups. The other (possibly better) choice is to post on some web page you have
access to and post a link in messages to the group.

In your case, I think working out the circuit of the charger and posting a
schematic would be better than pictures of the device. I have a technique that I
use to "reverse engineer" simple circuit boards where I start by scanning the
bottom of the board with my flatbed scanner. I can post a more complete
description of my methods if there is any interest.

Yes, please! We all hate having to do repairs and modifications without
a schematic. Anything to make that easier is well worth sharing.

Is there any problem with buying surplus jumpers, or salvaging them from
junk?

They can usually be straightened and bent again before the copper jacket
cracks, and they have the big advantage of having a connector
ready-installed on each end.

That was a good description of the Foster Seely discriminator. Do you use the circuit exactly as shown in the article as a phase detector when adjusting your tuner? That circuit has only one input and output. As I understand the circuit, you get an output when the input frequency differs from the center frequency of the discriminator. It will demodulate FM at the frequency it is tuned.
For this circuit to work as a phase detector wouldn't you have to split the input into 2 sections and apply the 2 signals you wish to compare phases. Then the output would be zero at resonance, one polarity with the current leading, the opposite polarity current lagging. Or am I all wet?

Looks like some sort of special contract, special purpose repackage of the SX28 made
by RCA, not Hallicrafters, likely for aircraft use. Strange. Probably rare, at least very unusual.
Probably a similiar situation to the later Collins military airborne repackage of the 51S1 by LTV.

2503. cheap RF switches

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-01 15:09:59 UTC
From: bertsch.3@osu.edu
Message-ID: <b6ca47$30f$1@layla.net.ohio-state.edu>
Source record: 36405

I'm thinking of using some ordinary DPDT toggle switches (the kind that mount in a 7/16" hole) to build a custom antenna/coax switch. It would only need to work at HF up to 100 watts max. My tests show these switches have a capacitance of 3-6pF between contacts, and between the contacts and the switch body. The breakdown voltage between contacts, and between the contacts and the switch body is about 2KV at 60Hz.

I can't think of any reason these switches wouldn't work. Any ideas?

Thanks,
Steve

I use the minature kind 1/4" hole in a changeover switch in my 100 watt mobile rig. I use it to switch the mobile antenna from the rig to an antenna analyzer. The unselected input is shorted to ground. Works fine for me.
The voltage and current capability of your toggle switches are fine for 100 watts. You will have a little more loss using toggle switches as opposed to a carefully designed coaxial switch, but at HF you won't notice.
I haven't done any a/b comparisons between toggles and other type switches at hf, but the toggles will work.

That may be true, but you've misunderstood what Tracy said.
Here's the entire quote:

"The converter had 5 outputs, one of which goes
through a circuit board and is supposed to be a
filtered output for a radio. That was why I though it
might work. Something is evidently wrong with the
board."

The "board", being the one "supposed to be a filtered output for
a radio"; however, Tracy figured that "filtered" meant the DC
would be stable and ripple free. That's is *not* what such a
filter would be for. It's a transient/noise filter designed to
keep voltage spikes and RF out of the attached radio.

The filtering Tracy was expecting would be provided by the
battery. The board doesn't have something wrong, it just
doesn't have a battery attached.

There ya have it! I think that is exactly right. Thanks Floyd.. I
think now it boils down to either using a battery with this supply of
scrapping the supply and using the transformer, case , and
rectifier....

I know quite a few people said to buy a supply that they are cheap
enough, but I would really like to learn how they operate by building
one myself. I never did expect this much feedback about something like
a PS, but it is really appreciated.

Ive built a 20 meter VXO an am using it to drive a sbl-1 LO to produce DSB. The VXO output waveform is not the best, in spite of all my efforts. The question is, how important is LO purity into these diode modulators. Should I lowpass filter the VXO output before feeding the sbl-1. Does it matter since the diodes switch on and off anyway?

No it would not. It violates the National Electrical Code; can
introduce objectionable ground currents, and, though improbable,
could possibly kill you.

Is 8' enough ... I can get a 10-12' rod if necessary? Is copper clad
iron OK or should it be pure copper rod?
>
> Is it OK to couple the common ground in the shack to the house wiring AC ground?

Not just "OK" - it's mandatory for your safety.

Source record: 36415

I've used small power relays for antenna and directional array switching for many years. The only problem I've had, and that you might have when using power switches or relays, is that you might have to transmit once in a while. Power switches, being designed for switching substantial voltage and current, typically have silver contacts. These oxidize or form other surface salts like silver sulfide. In normal operation, the power is adequate to burn through the layer, the arc cleaning the contacts each time the switch is thrown. If the switch or relay goes a long period without transmitter power being applied (that is, being idle or just being used for receiving), the contact gets erratic. A "dit" or two from the transmitter is usually enough to clean them. I've also found that WD-40 will extend the period they can go without transmitting. The contact pressure is adequate to make contact through the WD-40, but it inhibits surface corrosion.

The bottom line is that power relays and switches aren't a good choice for receive-only applications, but they're fine if you also transmit through them at least once in a while.

Jumpers would probably do fine...not quite sure where to find an
inexpensive source of them.

Turns out my immediate need has been resolved locally, but I sure
appreciate the inputs I've gotten here and via email. Thanks,
everyone!

I did find out that Down East Microwave sells several different sizes
by the foot.

I also found out from Precision Tube that their Coaxitube division is
no longer part of the organization...I discovered that by asking for a
catalog. The email they sent back said, "I am sorry, but Coaxitube is
no longer a company owned by our parent company, Mueller Industries.
I do not have any further information for you in regard to this." I
gather this is recent, since their website still has Coaxitube info

and a place on it to order the catalog! Maybe they will surface somewhere else. But of course, other companies manufacture semirigid, and in any event I'll probably be wanting to deal with a distributor and not a factory.

Cheers,
Tom

Source record: 36420

Switches designed for "dry circuit" operation are typically gold plated. I recall the period when gold prices escalated dramatically and manufacturers scrambled to find substitutes. Of the many substitutes tried, virtually all failed in the field sooner or later. So I remain very skeptical of anything but gold for reliable dry circuit operation. Virtually all properly designed contacts have mechanical wiping action, but often all it does with an oxidized (used loosely here to cover all kinds of surface salts, e.g., oxides, chlorides, sulfides) surface is to break and embed the surface layer into the underlying metal. Eventually, there's nothing but broken oxide pieces anywhere near the surface, and the contact fails permanently. This is particularly bad with something like tin, where the oxide is very hard and the metal very soft. Power switching actually vaporizes the surface layer with the arc, leaving it clean. The only way to avoid the problem without the cleaning arc is to make the contacts from a material that doesn't oxidize in the first place.

Some switches can be used for either power or dry circuit switching. These typically have gold plating over silver. However, if power is ever switched, even once, the gold plating is burned off and the switch can only be used reliably for power switching afterward.

Fortunately, we can be pretty casual about this for most amateur applications -- if a switch fails, we can just replace it. But making a product expected to work reliably without maintenance for many years requires a lot of attention to this kind of detail -- which, as you might have guessed, is how I came across it.

>Not just "OK" - it's mandatory for your safety.

A single ground point for everything has a number of advantages,
including safety. Ground loops caused by multiple grounding points are
very annoying to troubleshoot.

When we had the 40 year old fuse box at the electrical entry at my
mother's house replaced with a new breaker box, the electrician ran a
large wire (8 g I think) from the garage over to the part of the
basement where the water supply comes in the house, and tied the
entire house ground to that. This is an example of current (no pun
intended) NEC practice. Even if you do the electrical work yourself,
you need to follow code.

Assuming the water piping is metal, this works well, and can save you
a good bit of trouble.

Happy trails,

Source record: 36426

The distortion you are referring to is a symptom of a problem with the oscillator, and probably means the signal has excessive sideband noise that will affect its operation more significantly than its harmonic content.

The output of an oscillator grows until it hits a maximum limit. Most simple bipolar oscillators limit out by hitting a voltage saturation point. From what I read, this mechanism causes undue sideband noise due to a temporary drastic reduction in Q as it hits this voltage saturation condition.

For bipolar oscillators, current limiting operation is much more desirable, as it maintains the Q of the resonator. Oscillators with this behavior take some design expertise to make sure it works right and tend not to be the simple, straight forward, single transistor designs that are most often seen.

Simple FETs oscillators tend to work much better than bipolar because of a diode that is often used at the gate. This diode allows a charge to build up on the gate capacitor as the oscillation increases, reducing the gain of the FET until the ideal loop gain of one is achieved. The use of the diode hurts the sideband noise a little bit, but the resulting "gain limited" oscillator signal tends to be much cleaner than than the output of the correspondingly simple bipolar oscillator.

Bipolars can do very well, but usually require more design expertise to make sure it is operating under the correct conditions for optimum results.

The ARRL book "Radio Frequency Design" spends a lot of time on the ins and outs of various flavors of oscillators, including VXOs and is very recommended reading. You do not need to understand everything that is written there to take away some very useful information.

Beyond the sideband noise issue, any mixer will generate a lot of harmonics on its own as part of the switching/mixing process, so the harmonic content is not as much of an issue as sideband noise. If nothing else, a low pass filter can be used to clean a harmonic problem up especially if the signal has a symmetry problems.

Hi Richard,

Usually when referring to a filter being symmetrical, you are
referring to the slope of the filter skirts. A symmetrical filter
would have both skirt slopes the same. A non symmetrical filter would
have one skirt slope steeper than the other.

(snip)

As an interesting aside (to some, maybe), I was maintenance engineer
for a remote HF Rx site for the state govt. On that site we had about
forty separate single channel receivers, with the output audio signals
despatched via digital microwave bearer. After about two years of
stable operation with routine maintenance, we found reception
deteriorating fairly much across the board. We exhaustively tested
multicouplers, antenna systems and pretty much everything we could
find that was common to all receivers, but no joy.

Then we went to do a test through a receiver and disconnected the
mux-Rx cable at the Rx. (All prior testing had removed cables at the
mux end). Rx tested fine. Reinstated cable and proper Rx performance
returned. We then proceeded to remove and reinsert the RF connectors
on each Rx in turn until we had them all percolating nicely.

These receivers used SO239 for their antenna port. The connection
between the cable inner pin and the socket had gone high resistance
due to the total lack of any wiping current (not dissimilar metal
action). This was not an effect we had previously experienced in RF
connectors. The current maintenance schedule calls for these
connectors to all be removed and reinserted several times every six
months, and problems have not returned.

I'm not sure how useful this will be, because I use software that most people will not have. The main thing required is some photo editing software. I use PhotoImpact by Ulead which is similar to Photoshop but cheaper. There are probably many other similar software packages that could be used.

This is mainly for one-sided boards. Two sided is more difficult.

I put the board on a flatbed scanner and scan in color the circuit traces. Sometimes I use a digital camera to photograph the circuit trace side. Either will work.

I import the picture into my editing software. Using drawing tools I select a bright color different from the board color, like red. With the brush drawing tool set to freehand, I adjust the drawing size to about the dimensions of a pad on the circuit image. I place circles over each of the pads (transparancy is set to zero and soft edge is also set to zero to give sharp edges on the new circles and lines I am adding to the drawing.)

I set the pen to straight lines, reduce the size to smaller than the trace width, and draw connected lines over all the circuit traces. I also draw lines around the board edges and any other cutouts, holes, or features I want for recognizing locations. At the end of this I have all the circuit traces and features painted as bright red.

I use the magic wand select tool to select all of the red ciruits by color. (This takes only one tap on a portion of the circuit.) I now copy this selected circuit object into a new blank white image file the same size or larger. If someone has Photoshop, this process could probably be simplified by using its layer features to put the new circuit drawin in its own layer.

I now have a new image file which is the circuit traces only. I convert this to greyscale. I save this file. I flip that image horizontally to convert it so it matches the view from the component side of the board.

I print this out. This printout should be as large as possible. I examine the original board and, with a pencil, I draw schematic symbols for the circuit components onto the printout. When I have all the components and jumpers, etc. I can use this diagram to start working out the schematic in a logical way. Sometimes I use colored pencils to differentiate between types of components.

That's about it. You have to have some kind of photo editing software and be familiar with it, but after that its not hard to do this. Hope it helps some of you.

My, rather old, Collins mechanical filter catalog shows a series of "bandpass" symmetrical filters including the popular 455 kHz 2.1 kHz wide models; and a series of SSB asymmetrical filters, which are mostly a little wider - i.e. 2.7, 3.1 etc. In both cases they are available for IFs from 250 kHz to 500 kHz. There were also a series of multiplex sideband filters fro 60 to 108 kHz but they were bulky and not encountered in consumer equipment.

The asymetrical filters show a very steep characteristic on the carrier side and a much more gradual slope on the other side.

It seems to me that the symmetrical filters are used when you
move the carrier over from one side to the other of the passband.
And I would think that the USB and LSB filters are assymetrical,
because the carrier frequency stays put and you can thefore make
use of each filters assymetry. But, that's assuming the LSB and
UB filters are assymetrical and there's an advantage in that.

> content.

There are two distinct issues here: harmonic content and phase noise.
I believe the original poster was talking about harmonic content. In
a crystal oscillator, the close in phase noise is normally determined
by the intrinsic noise of the crystal, and the far out noise floor is
normally determined by the buffer amplifier following the oscillator.
Hence, oscillator design has little effect on phase noise in general,
and in any event, even the worst crystal oscillator still has phase
noise that is quite adequate for a 20 meter radio. It is far more likely
that if there was a phase noise problem, it would be due to noise
on the tuning voltage of the varactor used to pull the oscillator.

Harmonic content in oscillators can frequently be minimized by
taking the output through the crystal. For example, if the oscillator
is designed so that one terminal of the crystal is grounded, then the
connection from the crystal to ground can be replaced by a grounded
base amplifier, which has a few ohms of input impedance. The crystal
then acts as a crystal filter.

> Beyond the sideband noise issue, any mixer will generate a lot of
> harmonics on its own as part of the switching/mixing process, so the
> harmonic content is not as much of an issue as sideband noise

Here is a frequent misconception we see on the net. For optimum
performance, a mixer such as the SBL-1 should driven with a sine
wave LO. Any even order harmonics in the LO unbalance the mixer
and degrade IMD performance. Mixers don't generate even harmonics,
so the argument that "any mixer will generate a lot of harmonics" doesn't
apply. So why not drive the mixer with a square wave? Well, first
of all, you have to guarantee that the square wave is exactly "square"
ie, it doesn't contain even harmonics. Even if that constraint is met,
you then have the problem of getting the square wave to propagate
through the balun transformer in the mixer without distortion. The
phase shifts at different harmonic frequencies will in general be different,
so the diodes will not see a square wave, but rather a distorted mess.

> If nothing else, a low pass filter can be used to clean a harmonic problem
> up especially if the signal has a symmetry problems.

Now here is some good advice. Simply put a low pass filter
between the VXO and mixer. You will find that the mixer
works best if filter element nearest the mixer is a series
inductor, rather than the more common shunt capacitor.
A little known fact.

Did you measure the VXO waveform driving a resistive load or an actual SBL-1 mixer ? The mixer LO port does not necessarily represent a clean constant resistive load during the whole LO cycle during the diode switching periods. In the worst case you may have a variable resistance and/or variable reactance in parallel with the frequency determining reactances of the oscillator, causing waveform deterioration and phase modulation (phase noise). A buffer amplifier or at least an attenuator pad will reduce the effects of this variable load to the oscillator.

==========
For your information ,I am using a Thandar - Model TC200 LCR meter with 3 1/2 digit LCD readout ,made by Thandar Electronics -Huntingdon - Cambridge-shire - UK ,its minimum cap range is 0 -200 pF (stated uncertainty +/- 1 % + 1 LS digit).

The instument 's test condition is 1 kHz and 100 mV.

I am happy with the instument ,but even with cap stuck directly into the instument connections (hence without test leads) ,I have to accept it that a cap of say 10 pF can not be measured with an uncertainty better than 10 %.

It should also be realised that the capacitance will change with frequency as can be shown for example when measuring the capacitance with a MFJ antenne analyser while changing the frequency.

> one of the amateur radio magazines had a how-to article.

QST, March 2003, has an article by W5TOM about a homebrew shack microphone in which he achieved some improvement in clarity using bass and mid-range boosts. So, I cannot see any reason why similar results could not be obtained with an in-line equaliser such as yours. On the receive side it might help as well. Not as good as a DSP box perhaps but at least worth a try.

Cheers - Joe

I used to like it until they changed the way it worked a month or two ago.

They used to have just a single text field where you enter your keywords, and a switch to select "Exact Phrase", "All The Words", etc. Now you have to enable a filter with its own text field. This means you have two places to enter your keywords, the main (original) field and the filter.

The 'original' field seems to be stuck on 'Any Of The Words'. If you leave it blank and enter only in the filter, it tells you that "" (null field, no characters) is Adult Content (I will say that is one thing they got right, you can select the degree of protection you want). So, you have to put your keywords in both fields...

An example. Yesterday I wanted to search for High Impedance Headphones, with "High Impedance" being an exact phrase. What it gave me was web sites for 'High', 'impedance', 'High Impedance', and 'Headphones'!!

And it said that the search was done on:

high impedance headphones "high impedance" headphones
^^^^^^^^^^^^^^^^^^^^^ any of the words
^^^^^^^^^^^^ exact phrase
^^^^^^^^^^^^^^^^^^^^^^ all
of the words

Anyone know how to make this work? What other search engines do people use (besides Google). Google is ok for searching archives, but I don't care for it much for searching the web.

I don't like one-line search forms of any description. For complete
control over what to include *and* exclude at the same time, try:

Web - http://www.google.com/advanced_search

Newsgroups - http://groups.google.com/advanced_group_search

Actually they're not "advanced" at all - just perfectly clear.

2542. Measurements 59LF grid dip ??

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-02 15:13:00 UTC
From: Henry Kolesnik <wd5jfr@oklahoma.net>
Message-ID: <v8lvg3ibbm7l8c@corp.supernews.com>
Source record: 36444

For my Measurements Model 59LF grid dip meter I'm still trying to find a manual or copy and hopefully a 50kc to 100kc coil or an old orphaned LF coil form with the ferrite. The form was made by American Phenolic Corp, Chicago, Part No. 24-5P. The base is like an old 5 pin tube and is a clear cylinder about 1 1/4" diameter and 2 1/4" long, "pill bottle". The coil form, a ferrite cylinder about 1 inch diameter and 3/4" long is inside the "pill bottle" . I'd guess there's several hundred turns of litz wire wound pancake fashion with 5 leads coming out. The .1 - .25 MC coil wire uses about 3/4 ths of the ferrite length and the turns stack up to about an 1/8" thick. It's well designed and well made and has some weight to it. The unit has 3 additional coils, .25 -.55 MC, .55MC - 1.5 MC, and 1.5 - 4.5 MC. All use the same form but with less turns, the highest freq. coil has about 1/20th of the turns. I'd rather find one covering .05 - .1 MC or an orphaned LF form for another frequency if I can because I think it would be a major endeavor to try make one as good as Measurements!.
tnx.

Yes ive terminated it with 50 ohms ....it looks ok, but i was
expecting a perfect sine wave out of a crystal osillator. Its a
2n2222 osc lightly coupled to a fet into another 2n2222 with a tuned
output and link coupled into the sbl-1. I was putting about 13dbm
into the LO input, ive padded this down to 7dbm and now the sbl-1
output looks much better, and looking at the LO input with the scope,
it looks much cleaner. I read you could put more than 7dbm in, but
when I do, with no IF modulation I see a ragged approximation of the
LO on the output. Im building a phasing ssb rig. Got the two sbl-1s
feeding a psc-2-4.

If I am understanding you correctly you are getting better readings than
the specs promise. If you can get a reading of +-10% on a 10pf test, then it
is worlds better than the error of 1 ls digit. That would be +- 9pf, which
for your test would be +- 90%. Any single digit reading would be totally
worthless since they already tell you that the ls digit isn't real.
thanks, John.

I'm new to ham and just beginning to brush up on my electronics so any helpwould be greatly appreciated.

Attached is a schematic for a microphone mixer with bass/treble controls that I found on the web and am thinking about building but have a question.

On U2 would the circuit not need a resistor in line from the output back tothe inverting input, as is used on U1?

It just seemed to me (with my limited knowledge) that without it the entire signal would be fed back to the inverting input and cancel all output fromU2.

If the resistor is needed would I use a similar value to R7 on U1?

Thanks for the help !!!!
Jerry

Message-ID: <v8mf8sj0ru65c3@corp.supernews.com>
Source record: 36353

I'm not sure what you expect to see. When you're properly driving an SBL-1 you should see a pretty square wave at the LO port, and a chopped looking waveform at the output. Most of the buffers I use following an oscillator have an output impedance considerably lower than 50 ohms, so I generally connect a 47 ohm resistor between the buffer output and the mixer. The buffer output usually looks fairly clean, but the SBL-1 input, on the other side of the resistor, is squared off due to hard diode conduction. The mixer needs to be driven hard enough to cause the diodes to switch, for proper operation.

Chuck Dachis shows one in his "Radios by Hallicrafters" book. He has it as a R-45/ARR-7. He says "Electrically this set is very similar to the SX-28 although it is physically very different." and "While both the R-44 and R-45 are relatively common it is difficult and unusual to find either with the tuning motor assembly intact." The R-44 is the same size as the R-45, but is based on the S-36 chassis. Dosn't look like either the R-45 or R-44 have push pull outputs.

2552. Need comments on xtal osc down converter for LF transmitter

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-02 23:22:03 UTC
From: la8ak.xnd@online.no
Message-ID: <3e8b6d78.201620364@news.online.no>
Source record: 36355

Planning to build an xtal controlled source for 136kHz based on the
xtal synthesizer principle, but it is unlikely
that I need more than one xtal. Have many xtals around 6520kHz and
this is the reason for choosing this set frequencies.
The output from mixer is 4x (136-136.5kHz) and I suppose filtering is
rather easy task so I would use a 455kHz IF
transformer
Need comments whether it is a very bad mixer (bias circuits are not
shown). It is important to have maximum signal out
but mixer products are supposed to be far away from this frequency, so
I just wonder if it is neccessary to make it more
complicated? A 40673 mixer is another possibility, it has very high
gain on such low frequencies, but I would rather
prefer bipolars if it is no reason for choosing something else. IC's
are no problem, but why use it if it is just foolish?

Just awaiting some comments before I start the deadbug method mounting
in the next days

See the schematic on http://home.online.no/~la8ak/90.htm

The early/mid-70's ARRL handbooks had a 2 meter
amp project. It used a MRF-240 or something like that.
I know it was in the 1974 handbook.

Part of the project was modifying a standard power relay for
T/R switching. It was something like a 4PDT relay with
long internal wires removed and jumpers added. Losses
were claimed to be 0.2 db or so at 2 meters.

For another option look in the DigiKey catalog for Omron
RF relays. They have some fairly low loss models in the
$6 range.

It has to do with the termination of the harmonics. A choke
output filter (recommended) terminates the harmonics in
an open circuit; ie it behaves as a current source. A capacitor
output filter terminates the harmonics in a short circuit; ie it behaves
as a voltage source. In the former case, the filter is forcing
a sine wave current through the diodes. The time varying impedance
of the diode is proportional to the logarithm of sin wt, which is
a well behaved function that approximates an ideal switch. In the
latter case, the filter is trying to force a sine wave voltage across
the diodes. In this case, the time varying impedance of the
diode is proportional to the anti-logarithm of sin wt. This is
NOT a well behaved function and it does NOT approximate an
ideal switch very well. Hope that helps. It's a little hard to
explain, but if you look at the voltages and currents in a real
circuit, it is really obvious which version works better.

Oh, the meter will read the same cap the same every time; you can zero
the leads first so you're only reading the cap--so it should work fine
if you need to match a cap.

Volume 16, "Microwave Mixers", only has one double-balanced
mixer, and it is in a waveguide structure.

Volume 19, "Waveforms", has a fair amount about balanced
mixers, but not in real "design" depth. A footnote refers to
Caruthers' paper.

According to the Index Volume, these are the only references
in the Rad Lab series.

I seem to recall references to "ring" modulators as early as 1918
or so, elsewhere.

2561. First use of diode ring DBM?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-03 07:14:26 UTC
From: k7itm@aol.com
Message-ID: <3200347.0304022314.32736f97@posting.google.com>
Source record: 36363

Hi all,

What was the earliest that the diode ring double-balanced mixer occured? I have a reference to it in the early 1950's and wonder if anyone knows of it before that. My reference points to a few earlier uses of a diode bridge DBM, as opposed to a diode ring, but so far it's the earliest I've seen of the ring.

(BTW, thanks to Rick Karlquist for his note in another thread about the best way to drive modern diode DBM LO ports.)

Cheers,
Tom

This is a good question. The 1953 ARRL sideband book has an article
from QST for June 1949 which shows a ring modulator using copper oxide
diodes.

I don't really have any earlier references, and can't think of anything
that would specifically mention something about this.

Over the years, I've seen plenty about the origins of diode modulators
being in telephone circles. But it's not clear whether the bridge or
ring came first. The 1958 CQ sideband book shows a ring modulator and
refers to it as "the classic circuit used by the telephone companies
for the land line ssb generators". It mentions copper oxide rectifiers,
and how hams had used such a circuit in the under 50KHz range.

It then shows a Collins ring modulator, which is slightly more complicated,
but does away with the transformers; it specifically mentions the KWM-1.

But this section on diode modulators starts off with the bridge modulator,
not giving any word on it's origins. And I don't recall ever seeing
a bridge modulator in ham publications.

A well known early reference is Caruthers paper in the
Bell System Technical Journal in 1939, the title is
something like "Copper oxide rectifiers in telephone
modulators". Also, the Rad Lab series has a whole
volume on mixers. Not sure if any of these are ring
topology though.

I seem to remember a circuit for a postage stamp 6 m transmitter published in 73(?) magazine somewhere around 1970. It used a single Motorola HEP 55 transistor that had to be filed down for size, a tuning coil from Piconics, a crystal from McCoy and 6 mercury batteries for power. The antenna was a 6 inch square of copper clad pc board and it was good for about 370 mw or so. The whole aim of the article was to get this transmitter to fit on a postage stamp and keep its thickness under 0.25 inches.

Does anyone else remember this and if so know where I can get a copy of that circuit?

I don't have easy access to Caruthers' paper, but do note a patent to
him, US 2,086,602, July 13, 1937. That one is for a diode bridge, not
a ring.

The Rad Lab book would be an interesting reference, especially because
the patent I have for the diode ring (2,695,988; Nov. 30, 1954) was
issued to a fellow who had worked at Rad Lab. Unfortunately, I don't
know if it's for work he originally did there or not...I think it was
subsequent to that.

Cheers,
Tom

It may be better to live under robber barons than under omnipotent moral
busybodies. The robber baron's cruelty may sometimes sleep, his
cupidity may at some point be satiated; but those who torment us for our
own good will torment us without end, for they do so with the approval
of their consciences. -- C. S. Lewis

2578. Re: Reed relay for HF

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-03 23:39:37 UTC
From: JLB <IHateSpam@nospam.net>
Message-ID: <Du3ja.31662$G6.4165@fe01.atl2.webusenet.com>
Source record: 36379

It depends on how it is activated.

Once many moons ago I tried using one on 2 meters. It was the kind with a coil of wire wrapped around the contacts (as if the contacts were a metal core). As I quickly learned, this acted like an RF choke and there was absolutely no signal getting through.

Other designs may have the contacts outside of the coil magnet, or sued a permanent magnet. I have a gang switch for an RS-232 cable that is like this, with a big clunky mechanism to move the permanent magnets, but I don't think it will work very well for RF.

What I would suggest is look at the Fair Radio web site. They usually have some relays designed for RF at reasonable prices. Other places amy also have some.

The reference to the paper by Caruthers is:
R.S. Caruthers, Copper Oxide Modulators in Carrier Telephone Systems, Bell System Technical Journal, pp 315-337, April 1939

He described 5 configurations of diode modulator, including the ring. He stated that by about 1931 copper oxide rectifiers began to be promising as serious competitiors to vacuum tubes in modulators. He went on:
"Since 1931 continued improvements in copper oxide regulators have rapidly increased their field of application until they are now employed in practically all of the latest types of carrier telephone systems.

The copper oxide rectifier was invented in ca. 1926.

> that circuit?

If it was 1970, and that seems a good guess, I'd say it was the
March issue, and it was 73.

It was written by Bill Hoisington, K1CLL.

But it was just a single transistor oscillator, nothing unique.
Around that time, Bill was playing around with miniaturization,
and the fact that he was filing down plastic transistor cases
is an example of that. You could just use common sense to
make something as small as possible. Note that it was just
an oscillator; unless you were keying the supply line for
CW there was no modulation.

2583. How to connect Laipac

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-04 06:38:13 UTC
From: Gavin Jacobs <notasnoball@inhell.com>
Message-ID: <pL9ja.13004$de.1619674@news2.telusplanet.net>
Source record: 36385

I have a Laipac RLP434A receiver module as described here:
http://www.laipac.com/Downloads/Easy/TLPRLP434A.pdf

I can get data on the digital output pin (#2), but I was hoping to also use the linear/analog output pin (#3) as a RSSI. I have
asked Laipac via e-mail, and even though they reply to my messages, I never get technical answers, so I'm hoping to find someone
here who knows how to use it. Here goes:

What are the electrical output characteristics of the Linear Output (pin #3)? Voltage? Impedance?
What is the expected behaviour of pin #3 w.r.t. signal strength?

Thanks,
Gavin

> 73 Gary N4AST

Answered via Email. I'll post a briefer answer here.
Essentially the circuit operation is the same, but
the primary is the center conductor of coax passing
through the center of a torroid around which L2 is wound.
The input is split via C8 which is connected to (and senses the
voltage on) the feed line, and L2 which senses the current and
converts it to a voltage. The secondary circuit is arranged
to provide DC, not AF out, by eliminating R1, R2 and C5, and
grounding the junction of L3, R3 and R4, and removing the ground
from the bottom of C4. Output is taken from the junctions of
CR1-R3 and CR2-R4 into a centering 50ua meter. With the exception
of C8, all the stuff to the left of L2 is not part of the circuit
I use.

Copper oxide "varisters" were used in the channel banks and for
Group and Supergroup modulators and demodulators use in L
carrier systems designed in the 1930's. That was also true with
K, J, and I think with N carrier too. C carrier was originally
designed with tube type modulators, and later was equipped with
varisters, but I'm not sure about the dates when that happened.

I'm not sure when the earliest of these designs was actually
done, and it may well have been in the late 1920's. By 1939 it
was an _understatement_ to say they were employed in
"practically" all of the lastest carrier systems!

The 1953 Green Brain ("Principles of Electricty applied to
Telephone and Telegraph Work") shows an example diagram for K
carrier that has ring modulators in the channel bank section and
a lattice bridge in the group section. (Note that the channel
banks for K carrier were common to K, L, J and N carrier.)

Interestingly enough, one of the major problems with L carrier
systems that were still in use up through the 1970's was the
increasing failure rate of those varistors. There were tubes in
some of those systems that lasted longer than the varistors!

Great stuff Graeme, with that lcd it would be nice to add a bit more hardware, a serial interface, using the LCD / buttons or excell to create the data and you would have a neat little arbitrary wave generator as well.

I'm looking forward to seeing the PIC FFT code when you get it on your site.

As someone else said, it's good to see some electronics here - more stuff like this may save the group (aus.electronics) from going to crap, which seems to be the aim of a couple of irritants....

That is a great project!!

Thanks..

Have a good weekend.

Just had a quick browse thru your webpages.

One area / projects I'm interested in, is digital recievers using either
cplds or fpga.
One of the smaller xilinx virtex fpga's is better suited as they have
internal pll.

Not sure where to start.

If anyone is after a good free book(online version) on dsp
http://www.dspguide.com/

Alex

N carrier did not use the channel bank It was a double sideband system The ON system used O carrier terminals to get twice the number of channels by using single sideband.

Hi Bill,

From the descriptions I have of N carrier, I don't see how that
channel bank could be used either; but what I based my statement
on was a specific sentence in the 1953 Green Brain (page 285).
The description of the channel bank for J carrier systems says,
"Finally, a general design and manufacturing economy is obtained
by using this same channel bank for other carrier systems,
including Type K, L, and N."

It is possible that it was used in some weird combination that
is not described (nothing that actually is described varies from
your comment above). Perhaps it is a typo and should not have
included N carrier in the list.

Hmmm... is there an errata sheet available for that edition? :-)

Cross-posted to: rec.radio.amateur.homebrew,comp.sys.psion.apps,comp.sys.psion.misc

Speaker Enclosure Design programme V2.0 for Psion 5/5mx

Primarily aimed at sub-woofer box design this program can in fact be used to design any loudspeaker enclosure box.

Use this program to design the following box types:

* Sealed
* Ported
* 4th Order Bandpass
* 6th Order Bandpass

The program comes with a driver database which initially contains 29 different loudspeaker drivers. You can edit this database and add your own drivers as you wish.

This program is free software, there are no time limits or disabled functions.

Please go to
http://www.geocities.com/andrew_and_deborah/Psion/Speaker/speaker.html
and help yourself.

Don't know of an errata sheet.

Maybe that referance to N and A type Channel banks was from the time when
N carrier was being used and the Labs was looking at ways to go single
sideband so as to get more channels on the same systems. It turned out
that they deigned a system to stack four chanel, O carrier, banks to get
more channels.

Out of curiosity, is there a website(s) that detail more of the old telephony carrier equipment?

My only experience with carrier was with military CF-1 and CF-2 bays...long-lived, stable and Very Heavy (for portable) stuff. That was in the early 1950s.

Ahem, that's a lot of suffering, just to make to that last one.

> Out of curiosity, is there a website(s) that detail more of the
> old telephony carrier equipment?

I don't know of any. That's one reason that when I retired I
went out and found a 1953 copy of "Principles of Electricity..."
We had them at almost every location I'd worked at (with the
White Alice Comm System, Alascom and eventually ATT Alascom)
over the past 30 some years. Just a really neat old reference
book. (WECo built the White Alice System for the USAF, and had
installed much of what existed at that time with the US Army's
Alaska Comm System, both of which eventually became Alascom
which is now AT&T.)

I've just purchased a 1938 edition on eBay (it's in the mail,
but hasn't arrived yet), which should have better information
about those particular system.

> My only experience with carrier was with military CF-1 and
> CF-2 bays...long-lived, stable and Very Heavy (for portable)
> stuff. That was in the early 1950s.

I'm not sure what that would have been. Do you remember who
made it?

I'll have to admit, nothing has ever been as much fun as WECo L
Carrier for me. It was ancient by the time I discovered it in
the late 60's, but even then it was an engineering marvel.

Source record: 36305

I am trying to get back into CW (I only learned it well enough to pass the test several years ago) and am also trying to get a friend or two to learn it, and would like to set up our HT's (Icom ICw32a's, to be exact) to send and receive cw so we can practice together. I am looking for a simple way to connect keys to the external mic inputs so that we can practice both sending and recieving code across a short distance. Are there any plans for this on the net, or does anyone know of an easy way to do this?
Thanks in advance for any help!!!

There is not much point in trying to key the HT transmitter on and off
for each element, since HTs generally are quite slow to start
transmitting. Trying to receive this kind of transmissions with an FM
receiver with the squelch open would produce some kind of "inverted"
CW, when the receiver noise is heard when there is no transmission,
but the receiver is quiet, when the transmitter is keyed.

One way around this is to key the transmitter in an inverted way. When
the key is down, the transmission is interrupted and the other FM
receiver will hear the band/receiver noise. When the key is released
the transmitter goes on and the FM receiver at the other end will just
get silence from the speaker. At end of the message, the transmitter
has to be turned off.

But as I said, the HT transmitters are usually quite slow to turn on,
so this is practical for only very slow transmissions.

A much better approach is to build an audio oscillator (e.g. using a
555) running at 400-800 Hz, the output is routed through the telegraph
key, it is then filtered and attenuated and feed into the microphone
input. The FM transmitter is constantly on for the whole message
transmission and the audio is only keyed. The FM receiver at the other
end will either hear silence or the audio tone.

If the rig can be configured to generate the European 1750 Hz repeater
opening tone with some key on the keypad, the telegraph key can be
wired in parallel with this key. The 1750 Hz may sound a bit
unpleasant in extended use.

Don't forget to turn off the FM transmitter at the end of your message
so that you will hear the response :-).

Many small HTs will heat quite a lot if the transmitter is on for
extended periods of time. Thus, if long messages or slow speeds are
used, it could be a good idea to run the HT at a low power setting and
at a lower operating voltage than normally.

Yes, I've started few weeks ago to put some details on mine, see

http://home.online.no/~la8ak/2t.htm and
http://home.online.no/~la8ak/33b.htm

Some time ago I tried to ask for documents where the product detector
was used first time for demodulating SSB on radio, but never really
got any replies to this, got a lot of answers referring to telephone
carrier systems invented in 1918, and it is perfectly prossible to
build a balanced modulator on 20kHz based on mechanical modulator
Those "ancient" carrier frequency systems were optimized in using few
tubes as possible, but still they filled up a room to cover only 8 or
15 telephone channels. It seems I should have collected more material
from work, and now the only instruments I have to use at work is a
portable PC and a car and we are not supposed to use paper and books,
earlier we had at least a tool-box

Have put some notes on my site http://home.online.no/~la8ak/89.htm
showing principle how you can reduce the loss resistance in the
crystal and achieve improved selectivity in simple xtal filters. It is
based on principles described by HP (Santa Rosa, California, site),
but as K7ITM Tom Bruhns mentions, it is a technique not interesting
for Agilent any more, since they achieve far better results with
digital circuits. Perhaps an idea to look at for those who still like
to experiment with analogue circuits?

> thanks, John.
> KC5DWD
=========
I should clarify and correct my previous message (see above)
On the above referred LCR meter a nominal 12 pF capacitor shows as 11.2 pF

With the uncertainty being +/- 1% of actual reading plus 1 least
significant digit (as per the manual) the actual capacitance is in between
11.2 +0.1+0.1 = 11.4 pF and 11.2 - 0.1 + 0.1 = 11.2 pF , hence the actual
reading minus 0 and plus 2%.

The early version of the meter I have ,does not include a 'zero' adjustment
to cancel out any measuring
lead capacitance ,but caps (and also resistors and inductors) alternatively
can be stuck directly into the instrument via internal 'blade type spring
connectors'.
I remember the price I paid (in 1987) for this still very frequently used
instrument was GBP 99.- (approx US$ 150.-)

Source record: 36310

Why not use audio modulation ?
Just use a code practice oscillator (CPO) with a speaker or use a keyer with a speaker and key the rig and send audio CW. Place the HT mic close to the CPO speaker. Use a clamp to hold the PTT closed.
Identify every 10 minutes in voice or CW.

We conducted a code practice net here in San Diego using this method. Works fine.

Keying an FM transmitter to send CW will send a carrier with no tone and with no BFO in the RX will result in just on off carrier

Source record: 36312

I did something similar recently. I was giving some traffic practice at a local RACES meeting, and I wanted to send a few CW messages. Since everyone tends to bring their HT's to this meeting, FM MCW seemed like the way to go.

In this case, I wanted a few canned messages. I also wanted to release the transmitter for a few seconds after each BT. I used a mobile rig to do the transmitting (powered off a gel cell), but the same idea would work for an HT.

What I did was to program a PIC to do the work for me. I used a DIP relay to key the transmitter, and used the PIC to generate a 700 Hz square wave tone. A 0.047u cap between the PIC output and the MIC input softened the tone enough and reduced the output to an appropriate level.

For your purposes, I would put some keyer code in the PIC (although if you are using hand keys this could be dirt simple PIC code). This sort of application of the PIC really whacks the parts count compared to trying to do something with discrete logic. All it takes is a 5 volt regulator with the requisite 2 caps, a microprocessor crystal, the keying relay, and the output cap, plus, of course, the PIC. I ran the thing off a 9 volt battery and added a switch and an on/off LED since there's no other way to tell when the battery is being drained.

Unfortunately, I don't have this circuit posted, and never even made up a schematic, the thing is so simple.

..

Western Electric, of course. :-) [good old Chicago...]

CF-1 was a 4 voice channel carrier system with a top frequency
of 12 KHz. CF-2 had four TTY channels and would work from
one voice channel circuit. At ADA in Tokyo those were used
for VHF-UHF backup of landline circuits.

Both were rack-mounted with the racks in transit cases. Sitting
upright they were a bit over 5 1/2 feet tall. Stable as a rock they
were...felt like crystal-controlled but not a single crystal in them.
CF-2s had built-in adjustment-test circuitry for the polar relays
in the TTY loops.

>I'll have to admit, nothing has ever been as much fun as WECo L

"Carrier" equipment was the first use of SSB communications
anywhere. It became associated with "commercial bandwidth"

SSB (4 voice-bandwidth channels in 12 KHz total) in the early 1930s, became part and parcel of such pre- and post-WW2 SSB radio circuits worldwide. Single-channel, single-user SSB didn't come into full force until after WW2.

The first carrier system I saw was from the 1930's or so and was three
channels in three nine foot relay racks. It used dry cell batteries for
bias.
The tube had round "globe" style envelopes.

Hi,

I have some commercial end fed dipole antennas. I trimmed them to length from the supplier trimming chart for 152 MHz.

When I sweep one with the RF sig gen and return loss bridge, I see the resonant dip at 152 MHz but it is only about 8 dB return loss.

If I may a simple dipole from some hook-up wire and sweep it, I get around 20-25 dB return loss.

Would someone mind explaining what is happening, is there a PI match or something required between my sig gen and RG58 Coax to improve the retrun loss.

Also, what is optimal length of coax (is it multiple of 1/2 wavelength or (1/2 wavelength x Vp) ?)

Thanks for any assistance.

David:

A center fed dipole is usually a pretty good match for coax (50 or 70 ohm coax). But an end fed dipole requires some kind of matching device because of the higher impedance (several thousand ohms) involved.

The antenna you have appears to be intended for end feed so it must have some kind of matching device incorporated into it. I wonder if it has to be adjusted, just as the length has to be adjusted according to the cutting chart. You might look in the instructions for information about adjusting any matching device. If that fails, look at the parts near the feed point for anything that looks adjustable.

If this is a mobile type antenna, the matching device could be a screwdriver adjustable capacitor inside the base of the antenna. If it is a base station antenna, it could be a capacitor or maybe a sliding section of transmission line to make the match adjustable.

Good luck,

Roger K6XQ

As Roger pointed out, an end fed dipole will have quite a high impedance. This has another effect as well. If there is any coax between your bridge and the antenna, there will be significant loss in the coax at 152 MHz, and that loss will be exaggerated if there is a mismatch between the antenna and the feedline.

In any situation, the "ideal" feedline length is zero, since this will result in minimum loss. If your antenna is mismatched, some feedline lengths can hide the mismatch at the transmitter, but the exaggerated feedline losses will still be there. This masking of the antenna can help transfer power from the transmitter into the feedline, but may not help the end result. Certainly, when everything is matched you have the best situation, and in this case, increasing feedline length increases the losses, but changes nothing else.

When things are not matched, then different feedline lengths will give you different measurements, but in most cases, those measurements will be somewhat misleading since the feedline losses can get quite astonishingly high, and the measurements you get will be correct, or indicate a lower than actual mismatch (and consequently lower than actual feedline losses), depending on the length.

..

Hello fellow 8 bit ancient computer buffs,

I have been using the basic SDK-85 unit for 25 years, and have built several similar units from scratch. I have made many adjustments to the original somewhat flakey and unstable monitor software.

If you use the TTY feature, here is what I have to offer,

A direct plug in 8755A (should work in place of 8355) that is running a baud rate of 1200 8 N 2, instead of the strange 110, 7 M 2 that was supplied from Intel. I have deleted the chiclet keypad support software completely, giving you nearly 1 kilobyte of free 'FF' space to play in. I have fixed the weird stack problems also.

I could probably supply the patches, typed on paper, a 2716 eprom, or maybe an 8755a eprom. Which would you desire? Any interest?

2628. Series diodes -- equalizing needed?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-06 22:46:41 UTC
From: snarflemike@yahoo.com
Message-ID: <20619edc.0304061446.2a6cbdac@posting.google.com>
Source record: 36331
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

In the "old days" when power supply diodes were used in series for higher voltage capacity, resistors and capacitors were used across each diode to equalize voltages. I've heard that this is no longer necessary, because modern diodes have controlled reverse breakdown a-la Zeners. So, is equalizing needed these days or not? If not, does that cover all typical late-model diodes that might turn up surplus (normal 1N4xxx, fast-recovery types, etc)?

Here's hoping it's true!

73,
Mike, KK6GM

2629. Surplus AT power supply turned into HAM PS

Newsgroup: rec.radio.amateur.homebrew

Source record: 36332

Hi Guys,

As I posted earlier (March/22) on this NG...

I just finished testing the modified power supply I got from
the trash.
I followed the procedures outlined on an article (in
portuguese)
http://www.qrvtotal.hpg.ig.com.br/repetidoras.htm

This mod is quite simple, involving only a few diodes and a
capacitor.

I found that this modified power supply is quite
noisy...Putting some split beads over the power cord
decreased the noise a bit.

The antenna I used however, was far from ideal. A 5m
telephone wire hanging from the 13th floor without any form
of grounding.

I was thinking about putting a 4u7 capacitor in paralell
with the output to reduce the noise. If anyone has another
idea, it will be welcome.

cheers,

I know this was the usual practice when 'top hat' type SI rectifiers
were used. Many years ago I built a linear supply using 1N4007's and
I did parallel each diode with a 470k 1/2 wat resistor and a .001 1000v
disk capacitor. I don't know if this was necessary or not, but the supply
worked just fine. I also used twice as many diodes as necessary (the
transformer
was about 2800-0-2800 and I used 10 diodes in each leg of the fw rectifier).
The filter cap used ten 330uf 450v caps in series.

Actually, the equalizing resistors is still a good idea, and still very
much needed with the 1N400X series. All ratings are going to vary a bit,
and vary even more if you mix manufactures of the diodes within your stack.
I have never ran the equalizing capacitors, as they seem to cause problems
more often than curing them, but the resistors are very highly recommended.
Controlled breakdown? You don't want to be anywhere near that part of the
operating curve.

2632. Wallman converter (Cascode amplifier?)

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-07 00:57:51 UTC
From: la8ak.xnd@online.no
Message-ID: <3e90caf6.40651450@news.online.no>
Source record: 36336

Some German articles from 1950 refers to the Wallman converter when they are describing 2m converters. The circuits shown are somewhat different from the usual cascodes in the way that full supply voltage is over each valve, instead of the half. It could have some relavance since we know that many triodes will not operate properly with less than 150V, while ECC84=6CW7 will operate properly with as little as 50V supply for each triode.

Suppose Wallman is not a German, the construction may have been desribed elsewhere earlier?

From W0IYH's QST index I found the following early notes:
Tilton "Using the Cascode Amplifier on 50 MHz" p.29 (Mar 49)
Cross "A Cascode Converter for 144 MHz" p.11 (oct 49)
Chambers "The 6BQ7 on 6 and 2" p.46 (cascode amp) (May 52)
Suppose they are the earliest notes, or?

Paulo,

First you need to determine if the noise is being radiated and/or conducted. The remedy will be different based upon the cause. Linear supplies don't have these types of problems and, if there is ever a failure, it can be very difficult to fault isolate a switching supply and may not be economical to fix it. I've never had a failure with commercial or homebrew linear supplies; switching supplies have had lower reliability in my experience.

73s,

Evan

My approach is/was to assume that at least one diode would go into reverse
breakdown and I added at least one extra diode in the string. I have used that
approach
a few times and have never had a failure.

Good luck.

I do have the printed assembly listing of the original SDK-85 source code.
It has a bunch of my hand written notes in the margins. The listing starts
at page 4, and goes to 47. I have maybe 4 additional pages of notes.

Also, I have some source code that I have written to program 2716/2532/
8755A eproms.

B.T.W. The original source code for the monitor came with the SDK-85
package. That was nice of them, because the monitor was a tad buggy.

Hi again,
Could I induce you to scan or copy the source code for the monitor and send
it to me? I'd be happy to pay copying/mailing costs.

P.S. I tried replying off list but your address bounces
Bob L.

There was an 8088 (or perhaps 8086) single board computer with an SDK
prefix. Steve Ciarcia wrote about it in Byte. Could that be what the
SDK-86 is?

The advice that "equalizing" components are not needed has been in ARRL Handbooks for several years now. A few years ago, someone asked this question to my monthly RadCom column, so I contacted the original author for more details. Also it has been discussed several times on the AMPS mailing-list (amps@contesting.com).

The need for equalizing components is history - literally. It all began because early silicon power rectifiers could easily fail by reverse breakdown, causing a destructive arc across the wafer. The diode would fail short-circuit, so if one diode in a series string were to fail, it would place more inverse voltage across the other diodes and the whole string could 'unzip'. At first these diodes were quite expensive, and it was unusual to find more than 400V PIV, so manufacturers did not build in much extra capability to withstand a mains voltage surge at the wrong part of the cycle. Instead they relied on equalizing Rs and Cs to share the inverse voltage along the whole string.

That has changed, in three major ways:

1. All modern rectifier diodes have an avalanche ("zener-like") reverse breakdown characteristic

2. Peak inverse voltages can be much higher - 1000V is routine (1N4007, 1N5408 etc)

3. They are now "as cheap as chips".

The avalanche breakdown characteristic means that if a 1000V PIV diode does break down, it acts like a "1000V zener" (not a short) so it doesn't stress the other components anything like so much. If it's part of a series string of diodes, the power dissipation during breakdown is limited by the reverse leakage current of the other diodes that have *not* failed, so a reverse avalanche breakdown is usually completely recoverable - you'll never even know that it happened.

All of these factors put together mean that it isn't necessary to use "equalizing" Rs and Cs any more. It's actually cheaper to use more diodes in series, so that in Gudmundur's words you never come anywhere near reverse breakdown. However, Gudmundur is also right to recommend *not* mixing diodes from different sources in a series string. If you care about reliability, then use new, branded diodes straight off the bandolier from the factory. These will be as close as possible to identical in reverse leakage, so they will be self-equalizing without any outside help.

One final point is that so-called "equalizing" components can cause more trouble than they're worth. If they are not rated to withstand more voltage than the diodes themselves, and if they don't remain closely matched in value through the entire lifetime of the equipment, they can have the opposite effect to what they're intended for! These days, it's actually cheaper to use additional diodes.

That's why the modern approach is not to use equalizing components. In "postmodern" power supplies, capacitors across diodes are coming back, but as part of an R-C snubber network to reduce spikes conducted back into the mains... which is a quite different motivation.

This is absolutely true, but don't forget to add NE-2 lamps with series
resistors across each diode. The actual transient suppression you get is
minimal, but it sure helps find the problem when a diode goes open.

> something required between my sig gen and RG58 Coax to improve the retrun
> loss.

Certainly I would not expect the same feedpoint impedance for an
end-fed half wave as for a center-fed half wave. Also, the end-fed
MUST be fed "agains" something. Whatever current you have in the
antenna must have a return path. Typically, it would be a ground
plane, but it might be another half-wave: a center fed full wave
doublet. In fact, with an ideal infinite ground plane, the feedpoint
impedance will be exactly half that of a symmetrical doublet in
freespace. I assume you know that the feedpoint impedance of a full
wave doublet is rather high (and quite dependent on wire diameter).
Expect to have some sort of matching device at the antenna to get a
decent match to coax, or else provide a matching network at the other
end of the line.
>
> Also, what is optimal length of coax (is it multiple of 1/2 wavelength or
> (1/2 wavelength x Vp) ?)

It depends on the mismatch at the antenna, what the line impedance is,
and what sort of network you have to work with for matching at the
other end of the line. If the feedpoint of the antenna is, say, 500
ohms resistive, then 50 ohm line can transform that to 5 ohms or to
500 ohms (actually a bit more than 5 or less than 500 because of loss
in the line), or something with the same SWR (return loss magnitude)
but with reactance. _IF_ you are operating at a fixed frequency, you
might find a line length that makes matching relatively easy. For
example, if you had that 500 ohm resistive load and 75 ohm coax, you

could adjust the length to n*180+27 electrical degrees and get a match to 50 ohms with a simple series inductance of about 140nH...or you could adjust the length to n*180+153 degrees and get a match with about 8pF series capacitance. But if your line is several wavelengths long and you want it to operate over a range of frequencies, things will be far easier if you match at the antenna end, because the impedance seen at the other end as you change frequency changes rapidly if the antenna end is mismatched. Also, line loss is higher for a mismatched line than for a matched line, and that can be a problem, especially for small (high-loss) lines run some distance.

(You can use any of a number of programs to work out numbers like I did above; I prefer the visulization I get from a Smith chart program, and you can even use just a paper Smith chart. But some people prefer to just use a numerical calculation program. In any event, it takes only a couple minutes to work things like that out, well worth the time saved mucking around with coils and capacitors trying to get something working by luck and experimentation.)

Cheers,
Tom

so it is likely that the amplifier is called cascode amplifier in US,
and "Wallman stage" in Europe in early 50's.... while European
articles around 1954 mentioned the 'cascode'

On closer examination I see that equalizing was recommended last in
the 1994 Handbook, while it is no longer recommended starting in 1995.

Thanks for the great information. I found the comment about the
equalizing resistors changing over time and making things worse rather
than better especially interesting!

Just think. Expanding from the Earth at the speed of light is an expanding sphere of television waves. And at the very leading edge are Howdy Doody and the McCarthy hearings. Not to say it's all that better farther inside the sphere. . .

2656. Interference from Allen Bradley Variable Frequency Drive

Newsgroup: rec.radio.amateur.homebrew

Hi y'all:

Has anybody experience with quieting the RFI of an Allen Bradley
Variable Frequency Drive for an air conditioning motor?
The unit adjusts the speed of the motor by varying the frequency
from 40Hz to 60Hz while keeping the voltages at 3 x 400VAC.
The electronic unit resides in a metal cabinet but the wires to the
motor are about 4 meters long and not shielded. The RFI is strong
from VLF up to lower VHF. It is pesting the vicinity in a range of
about 100m and that's where I live. FM is not so much of a problem
but AM/SSB is.
Our nominal voltages are 230V/400V 50Hz.
I have access to the unit and can get the HVAC guys to work on it
but maybe some hints will save us some hours/days of experimenting.
Thank you in advance.

Kind regards, Eike

Sounds like a Really Good First Thing To Do is to wind the wires
through a ferrite toroid (or two or three) a few times. RatShack makes
one that snaps open, for just this purpose. If you can get 'em to do
it inside the cabinet, so much the better, as this will mean that
little or none of the hash will get outside the cabinet.

RF bypasses from the phases to ground inside the cabinet also would
be good, if there aren't some there already.

Well, lessee... Assuming local electrical codes allow it, how about
a grounded shield braid over each of those motor power leads? Or perhaps
bringing the motor's power leads through feedthrough caps in a grounded
metal enclosure?

I'm sure others will have other suggestions. Good luck.

Hi Roy,

Expanding on that theme- would ET's then conclude that the human race peaked about the time the sphere of the Dick Van Dyke show passes them, and has diminished since then?

> the random wire to a valved cathode follower circuit and match your coax
> line this way?

Yup! A number of commercial receiver distribution amplifiers, and
active antennas, did just that. They often also included a filter or two
to block big signals from the AM band though. A triode such as the 3A/167M
(417A?) was commonly used - biassed for lots of current.

Cheers - Joe

I had some experience with these drives in an industrial situation.
The biggest bang for the buck was adding a common mode choke very
close to the drive on the T leads. We started out with a commercial
unit, but had to design our own with a lot more ferrite core material
to get the effect we needed. The concept is to have the 3 T leads
(twisted together) pass through a high permeability ferrite core one
or more times. We made a core out of 4 stacked 2.5 inch OD, .5 inch
thick toroids. There may also be some advantage in putting one on the
AC supply leads (or feeding the AC through a 5%, laminated iron core
choke), but the noise is mostly radiated from the T leads, since they
are driven with a fast rise time waveform.

If you want help selecting a core to build your own common mode choke,
email me.

Got one myself... would love to have any updates and SDK-86 information
you could/would provide.

I would be happy to provide free eprom programming to anyone who needs it.

I would be willing to post any related information on the
http://sonic.ucdavis.edu web server which might include down loaded
files.

One of the things some of you 8085 guys might like to know is that Enimac
(hope I spelled it right) made one hell of a similar 8085 trainer which is
probably still available.

It's hands down better than the SDK-85, but I'm an 8085 nut so I like them
both. The Enimac trainer has all the source code and hardware laid out...
includes some software and enhancements.

I found a company in Canada call Micept Making nice/low price
editor assembler packages for all the smaller processors in the mid
90's... bought the whole package for less than $150 us.

Of course, the famous ACC RC-85, RC-96 and RC-850 Amateur Radio Repeater
Controllers were 8085 processor based.

cheers
skipp

2667. 900MHz Tx help, anyone please??

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-08 18:34:15 UTC
From: FrankRF2@cableone.net
Message-ID: <rf569voj08nf1a5ighln2b7ldsm7a3ap12@4ax.com>
Source record: 36270

Hi,

Saturday I jumped at a deal at a garage sale and bought two 5"
Remington monitors ($5 each) thinking the RCA plugs on the back were
Inputs. After getting home and doing some testing it turns out they
are outputs. It has a switch to select input freq C1 and C2. I got
online and found a spec sheet that says,

Transmitter:
Frequency
Input C1: 907MHz ± 0.5MHz
Input C2: 922MHz ± 0.5MHz
Transmission power: 94 dBu (FCC Spec)
Frequency stability: ±1MHz
Harmonic Radiation: <960MHz 46dBu Max(3m)
960MHz 54dBu Max(3m)

I need a video transmitter to hook to the ice-cube camera RCA jack to
send the signal for the 5" to pick up and display.

Any suggestions for who/where I might get a kit or circuit to build
some Tx's??

Thanks in advance.

I would think computer supplies are to some extent counting on
being in a metal computer case (in addition to it's own case),
so they are less concerned with the output wires radiating than
switching supplies intended for powering radios.

I wonder how much signal radiates out the vents for the fan.
Covering it with some fine metal screen might help.

I can't help but think that some of the schemes for reducing
noise in cars that you'd see in old books might be applicable.
Get some high value feedthrough capacitors, if you can find
them, and mount them on the supplies case, feeding the output
lines through them. In that sort of situation, there might
also have beena small box over those feedthrough capacitors,
with some small inductors, and then maybe a second set of
feedthroughs (ie a lowpass filter) out of the smaller box.

For that matter, one might strip an unneeded switching supply,
they are cheap to find as junk, and use the toroids to build
up a better layer of filtering on the output of the supply.
I'm not even sure they put low value bypass capacitors in
parallel with the electrolytic filter caps at the output,
which might be worth doing to bypass the high frequency
harmonics.

Usually, those supplies have filtering on the AC line. If
not, one can buy AC line filters that are built into those
power jacks the supplies use.

Maybe, if they aren't there, putting 0.01uF capacitors across
the diodes in the bridge rectifier at the input might help.
Considering I now won't build linear power supplies without
those caps, having seen their usefulness, it perhaps will
help if the noise is coming out of the line cord.

Another scheme was to put a tuneable filter in series with
the +12 line out of the alternator; one book said resonate
it at 28MHz. It acts as a notch for AC on the DC line, and

presumably at that frequency because it was more troublesome there. If there's one particularly obnoxious signal out of the power supply, and it's coming out the output line (rather than radiating from the case, or coming out of the AC line), maybe a tuneable LC circuit would help.

I seem to recall mention of one commercial supply having some means of adjusting the supplies switching frequency, in case a harmonic lands at a desired frequency. This makes sense, though I'm not sure if I really read it, or simply imagine it.

Jason:

Though the list you provided was pretty reasonable, it would cost a chunk of change to stock all of the items you mentioned, and you still would be looking for more. Many years ago, when I was in the Army and was sent to Korea, I put together a somewhat similar (but much smaller) list for the year I was to be there. As I found out once I arrived, many of the parts were available there, though I needed to look around a bit and take some additional care in selecting components, as their markets are rather different than the surplus, electronic and ham stores (and online purveyors) we are now typically used to using.

What I finally learned is that I should stock up as I need parts. To explain a bit, I don't actually go looking for parts between projects, but if I encounter a good deal, I'll add to my stocks. Usually, when I start a new project, there is a need to purchase a few parts that I don't have on hand, and I'll look around to see what's available. Often, there are other bits and pieces that I could use for the "junk box" that I don't already have, and I tend to stock some of these items when I purchase items needed for the current project. This helps to take care of any minimum order issues, while at the same time, building a stock of common parts that I can use later. The only problem is that my needs have tended to change over the years, and what I thought was going to be needed (ten years ago) is something rarely used today in my projects... Times change, and so do we. Of course, there have been a few times I really wish I'd stocked up on a particular part when it was really cheap, because now it's like it's made from unobtanium, but that's the problem with some things. However you do stock up on your parts, you should realize that it may be false economy to stock large numbers of electrolytic capacitors, as they tend to "dry up" or otherwise lose capacitance over the years... I'm sure there are other parts that age sitting on the shelf, but none I've been personally bitten by in the past couple of years.

Now, if you are stocking for a doomsday scenario, where you believe that there won't be any parts suppliers any more, and you want to be able to repair the equipment you now have, I'd be stocking just about all of the parts that are currently used in your equipment first, before other general supplies. I'd particularly pay attention to proprietary devices, or components that are likely to become rapidly obsolete, or have not been used in a lot of other radios that might be scavenged for the parts later. Whenever I purchase a relatively antique piece of equipment, I tend to create a stock of replacement parts for at least the more likely failure items, just so I have them on hand. This is more for my own convenience than any worry that society is going to collapse any time

soon. Besides, where I live, if we encountered some large, global
catastrophe, like a really big meteor dropping out of the sky, I would
probably be one of the first washed into oblivion, so I probably wouldn't
have to worry about surviving the following years after civilization
collapses....

Good Luck

2671. Transformer help

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-08 23:23:31 UTC
From: Shephed <roll1up@smkey.com>
Message-ID: <TRIka.54003$JI.14422952@twister.neo.rr.com>
Source record: 36273

Hello all,
I'm putting together a single 6T9 tube project for a QRP club.

In working with an old ARRL article, it's calling for a Stancor PC8401
filament transformer.

Can someone give me the specs on this transformer and a good source for
getting them.

Thanks es 73
Dan, N8IE

2672. Linear amp DC input Vs Output

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-08 23:46:42 UTC
From: enigma_y_2000@yahoo.com
Message-ID: <3e935ef5.16696958@news.usfamily.net>
Source record: 36274

Hi,

Is it possible for a linear amplifier to have normal DC input power to the final tubes, but to be way low on output power delievered to a dummy load due to weak tubes? Yes, I'm loading it properly.

Or will the weak tubes always show up by not loading to full DC input power?

Thanks,

Bob

2673. Hombrewers: What parts do you stock up on?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-08 23:47:13 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0304081547.6625eea@posting.google.com>
Source record: 36275
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

I posted this thread on the eham HomeBrew and Elmers forums. I want the input of all the experienced homebrewers here.

What electronic parts do you stock up on? I have noticed in building a few projects and especially from looking at the designs of many more that any decent homebrewer will use certain parts on a regular basis. I believe that any experienced homebrewer has a substantial inventory of common parts and makes sure to stock up when either ordering other items or when attending hamfests. It's frustrating to lack a certain critical part, and many of them are not available at Radio Shack. (Come on, try to buy a Germanium diode or SMA connectors at Radio Shack.) Every order to Digi-Key or other online/mail-order vendors will have shipping charges added on. There are also parts that are available at Radio Shack but at exorbitant prices compared to Digi-Key and others. (LM741s, LM324s, and SO-239s come to mind. Don't try to tell me that these are rarely used and that no homebrewer stocks up on these.)

So I am compiling a list of items that any homebrewer should stock up on. Please excuse the mis-numbering, as it would take too long to fix everything. Yes, I know that you can't have every part possible. However, certain items are used on not one project but many, many projects. For example,

General items:
1. DC jacks
2. DC connectors
1. LM3914 display driver ICs
2. LM3915 display driver ICs
3. 1N34A germanium diodes
4. Zener diodes
5. 1/4" LED holders: available at Radio Shack
6. 1/4" LEDs (red, yellow, green): exorbitant prices at Radio Shack
7. 9V battery holders: available at Radio Shack
8. Nylon binding posts: exorbitant prices at Radio Shack
9. Chasses (metal and non-metal): available at Radio Shack, but more selection and better prices elsewhere
10. LM324/358 IC amplifiers: exorbitant prices at Radio Shack
11. LM741 IC amplifiers: exorbitant prices at Radio Shack
12. .001uF capacitors: available at Radio Shack, but not at the best prices
13. .01uF capacitors: ditto
14. .1uF capacitors: ditto
15. Electrolytic and tantalum capacitors: ditto

16. Mica capacitors: ditto
17. IC sockets
15. LM317 or other voltage regulators: available at Radio Shack at high prices
16. Switches: available at Radio Shack
17. Circuit boards: available at Radio Shack
18. 2N2222As: available at Radio Shack at high prices
19. 2N3904s: available at Radio Shack at high prices
20. 555 timer chips: available at Radio Shack at exorbitant prices
21. 2N3906s
22. 2N2907s
23. Shrink wrap (for soldering wires onto LEDs): also available at Radio Shack and Home Depot
24. Solder: ditto
25. Solder flux: ditto
26. #30-gauge wire wrap wire (for wire wrap projects or RF transformers if distributed capacitance is an issue and you don't like magnet wire): available at Radio Shack
27. 1/2-W Resistors: available at Radio Shack
28. 1N914/1N4148 diodes: available at Radio Shack
29. #6-32 nuts and bolts for mounting circuits: available at Home Depot as well as Radio Shack
30. Potentiometers
31. Knobs
32. 2N2219 and 2N2905???
33. MPF102/2N3819 or similar FETs???
34. 2N3055 or other power transistors???
35. LM723 for power supplies???
36. Assorted powdered iron cores T- 37/50 - 2/6 ???
37. PCB material ???
38. BNC connectors/jacks

Audio items:
1. LM386 audio amp
2. Assorted audio connectors (RCA, 1/8" phone plugs)
3. 5532 op amps
4. Complementary output transistors that can handle some power

RF items:
1. FT50-43 ferrite toroid cores: useful for many, many RF projects
2. #73 ferrite beads for connecting RF and DC grounds
3. SO-239 jacks: available at Radio Shack at higher prices
4. PL-259s (make sure to get the right kind for the cable): ditto
5. SMA connectors
6. RG-58 coax for jumpers: exorbitant prices at Radio Shack
7. Lower loss coax
8. Mixers (for homebrewing transmitters and receivers)
9. 2N3563/MSP-H10/2N5179/BFR-96 or equivalent (for VHF)
10. 2N4427/2N3866 1 watt VHF finals (for homebrewing transmitters and receivers)
11. 1 - 10pf piston trimmers (vhf) ???

12. trim caps about 80pf max (hf) ???
13. IF transformers: 455 kHz and 10.7 MHz (can be rewound for other frequencies) ???

I keep an eye out at hamfests and fleabay for:
Hammarlund variable caps of the "MC" type (both centerline and
offset types). Dip mica caps when available in bulk cheap.
Filter chokes, small audio transformers and power transformers.
1/4, 1/2 watt resistor assortments. Small signal transistors, linear
IC's both op amps and rf/audio types. Crystals, rf chokes, adjustable
core coil forms (transistor IF size units with mini slug adjustment, can
be rewound to desired inductance).

I've got some un-usual junk in the junkbox that I thought I could use.
Several
old turret 'standard coil' tv tuners. Two of them could be ganged and
fitted
with torriod core coils for a 12 band radio front end. A box filled
with ceramic
and fiber rotorary switch sections plus some used shafts and index
assemblies
(the switch sections are mostly unused, everything else from junked
switchs) for
custom switches. IF cans from old radios, tv's and military junk.
(several from
bc453's @85 khz, the rest from bc454's @1415khz). Old AA5 two and three
section variable caps and some mini's from transistor sets, some AM/FM.

Guess I'm just a pack rat. Anything I can find, especially if in bulk
and cheap
I'll pack away for a rainy day.

I will rarely buy any parts at rat shack EXCEPT for when they have
'special purchases'
of good stuff cheap, or the store manager is dumping surplus stock being
discontinued.
I got a bag full of GI sound generator chips that way at rat shack.

I searched with google and could not find anything specific on
a Stancor PC8401 transformer.

However, there is a data sheet for the 6T9 tube at

<http://www.qsl.net/wd4nka/TOOLS/Manual/6t9.html>

And it says the 6T9 needs 6.3 VAC at 0.93 Amps for filament
power. If that tube is all that the transformer is powering,
any 6.3 volt filament transformer for 1 Amp or more will do
the trick.

Hi Guys;
I have for Sale:
a few of these gear driven air variables that my Digital B&K RLC bridge shows it as 45-180pf.
They are new old stock.
4"l x 2-1/2"h x 3"w.
Box was marked for BC-696A, 1946(?).
Price is $10.00 ea plus 3lbs shipping from 11758
Pics>>
http://www.myradioroom.com/45-180pfgearcap1.jpg
http://www.myradioroom.com/45-180pfgearcap2.jpg
I finally found a large stash of caps, some new, some used & all sorts of values. Pse e-mail me if you need others.

Thanks & 73,
Rich WA2RQY(1961)

I think you are right. I don't said explicitly, but I have
no AC ground. So it doesn't matter if the metal case was
intended to block the radiating energy, since it is
insulated from ground. (no good here)

> I wonder how much signal radiates out the vents for the fan.
> Covering it with some fine metal screen might help.

At 33kHz, the wavelength is much bigger than the fan hole...
It is not a real hole, but the case is _well_ vented in that
spot. IMVHO, it may block even some microwaves...

> I can't help but think that some of the schemes for reducing
> noise in cars that you'd see in old books might be applicable.

You DID help, if nothing else, now I have something to read
about...
Thanks for the help, Michael

My finding has been that the efficiency will drop maybe 3 to 5 percent, but that is hard to know unless you have kept careful logs of the amp over time. You will find that 'PEP' will have dropped 20 or 30 percent, while the 'average' output appears to have dropped far less. I have often found that weak tubes just won't draw current on the higher 'low' bands. Power output will be terrible on 10 mtrs, but only somewhat lower on 80 mtrs.

One thing for sure.... If you put power in, and don't see power out, you shall surely notice brightly glowing anodes, followed shortly thereafter by screams when you price new glass finals, or, you get to enjoy the smoke and flame of an RFC with a shorted turn or two turning into a flaming slag pile. I had a 'low output' amp do that to me.

|I'm putting together a single 6T9 tube project for a QRP club.
|
|In working with an old ARRL article, it's calling for a Stancor PC8401
|filament transformer.
|
|Can someone give me the specs on this transformer and a good source for
|getting them.

Specs yes:

High voltage 235-0-235 @ 40 mA DC.

Rectifier Filament 5.0 VAC @ 2 A

Other Filament 6.3 VAC CT @ 2 A.

Source no:

The above data from a 1961 Stancor catalog (never throw anything away
<g>) so your chance of buying one is nil.

Almost any old radio with a power transformer (non-AC/DC) should yield
something suitable. This is homebrew after all.

It depends on how you define "weak" tubes.

A tube that has low cathode emission will have difficulty
loading up to full DC input power, because it can't supply the
current. (Other physical problems, such as a fried screen grid,
could cause the same effect.)

A tube that is gassy will show high current, but low output. Just
the opposite of above.

From Ham Fests :-

All the stuff that is no longer available or very expensive new.
Mostly QRO for linears and ATUs

Ceramic standoffs
Vacuum relays & caps
High voltage paper in oil caps
mica caps.
Ceramic wafer switches
Die cast boxes
19" rack boxes and panels
big HV transformers
feed-through caps, threaded for preference.
ETFE jacketed silver plated copper wire
coil and bar roller coasters
BA nuts and bolts
Turns counting dials
Heliax
FSD <= 100 uA meters

From current suppliers :-

OA47s
Shottky diodes
Ferrite and dust iron toroids
BNC and N type connectors

vy 73

Andy, M3ABC

Whoa, be careful of using .01uF on a switching supply across the diodes. At 60Hz, they're fine. A switcher runs at anywhere from 100KHz to 300KHz. Think of what that cap is going to look like at that freq. You'll probably need to do some math here to find the most favouable value.
You can always bring out the power in shielded cables. ;-)

If switching power supplies do NOT have isolation transformers, do such supplies isolate the output(s) from ground?

Normal house pole-pigs produce a 120-volt "phase" (not sure if that is the correct word) on either side of ground/common. If a house is well-wired, both phases may be present at wall outlets in any particular room. If one plugs a computer into one phase and another computer into the other phase, are their power-supply outputs (including ground or chassis) at the (approximate) same potential, or might there be 120 volts difference?

Yes they are isolated. The main oscillator is not, but there is a high frequency transformer to develop the outputs.

Yes it's safe to plug computers into different phases; the outputs are still isolated.

To phrase it a bit differently..

Switching power supplies in computers start with a rectifier right off
the power line. This then drives a power oscillator operating at a
relatively high frequency. (tens of KHz)

This oscillator, in turn, drives a transformer. This transformer
provides isolation.

So the circuitry on the primary side of the transformer - the rectifier
and power oscillator - is not isolated. You must take appropriate
precautions when working on it. However, the secondary side - the one
that's connected to the computer's chassis - *is* isolated, through the
transformer, just as if a standard linear supply w/60Hz transformer was
used.

(WARNING! This applies only to computers. I have seen plenty of other
devices where the switching supply is NOT isolated from the power line!
TV sets come to mind.)

Computer switching supplies do have an isolation transformer of a sort. The difference is that it is operated at the switching frequency, so it is relatively small. Isolation for regulation purposes is usually by virtue of an optical coupler.

Normal US house wiring in urban areas is "split phase" consisting of a neutral, and two "hot" wires 180 degrees out of phase. The voltage between the two phases is twice the voltage between the neutral and one phase. However, the "ground" is a different animal from the "neutral." While it is true they are connected together at some point, they are considered separate entities. The ground conductor on a 3-wire cord is indeed usually connected to the chassis of your typical computer power supply. The neutral, however is not, and therefore EVEN IF YOUR OUTLETS ARE WIRED INCORRECTLY, as long as the ground pin maintains its integrity it is impossible to have a potential difference between two computer chassis. If the ground is unconnected or defeated, you still would not be able to have lethal potentials between chassis, but there could be considerable leakage through the line filtering networks.

If this doesn't answer your question, write me directly.

Hi Jason,

I have a full storeroom, but it did not come through an introspection of building and filling an ark.

No, I observe a simple rule of construction in each of my projects for various customers: buy for three units, build two, deliver one. Odd as it may seem, the extra parts from any previous project rarely find their way to the next. As such the parts on store have grown through accretion. About the only things that I do stock and rotate are of the lowest of low tech: nuts, screws, washers, boxes.... They are closely followed by the next rung in order: knobs, switches, connectors, fuses....

As for your exhaustive list (seems to me I recommended a suite of ferrites for your SWR meter project), that was too long by half being dominated by the high end of tech (you need a wider variety of caps and resistors if you are going to put the linear chips to work).

Another rule while I've got the soapbox: design to the smallest number of connections or try to force those connects into a smaller package. This means fewer parts, and if you haven't smelled the coffee yet, digitize as quickly as you can. Connections are expensive.

My design for the Black Box monitored several dozen parameters through sensors placed throughout the airframe. These sensors each had at least two lines, if not more (there were a lot of synchro/servo lines), and all of those leads arriving at my backplane passed through two 300 pin connectors. Those two connectors alone cost about $2 a pin. These suckers were specified as ZIF (Zero Insertion Force) and yet it took two men and a boy to seat them. Of these 600 leads, few were digital, maybe 2 or 3.

Once inside, you would find little evidence of linear design. I did not have an energy budget for their individual conditioning. I did not have a heat budget to support conditioning if I could. I did not have a volume budget that would allow all that circuitry anyway. No, the only physical evidence of deference to linear signals was found in resistor/capacitor pairs to cut down on HF noise - then the signal was

immediately sampled and the rest is digital history.

Without having taken the fast lane to digitization, I would have had to designed more connections to support what was demonstrably unneeded: signal conditioning. This is not to say I abandoned it totally. There were the snubbers mentioned, but I also had several linear circuits that were multiplexed (again, cut the number of components and connections).

To put icing on the cake, I still have samples of the processor, ADC and DAC's, multiplexors (low "on" resistance cross point) and Op Amps from the crash recorder sitting on the shelf in the storeroom. I've yet to figure out how to put them to work on the "current" project.

Let me rephrase my earlier post. For those who want to hook the HP 8444A tracking generator to their 8590A spectrum analyzer, the trick (besides having option 059 on the tracking gen) is:

--Connect a short BNC-ended 50-ohm jumper between the '500 MHz LO Out' and 'Third LO In' jacks on the back of the generator.

--Run another BNC-ended 50-ohm cable from the SpecAn's '1st LO Out' jack to the generator's '1st LO In.'

Calibrate the generator output, and Viola! You're done!

2702. PCB Software

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-09 20:51:49 UTC
From: Dick <dick@langwang.demon.co.uk>
Message-ID: <DwdMmwBlfll+EwL9@langwang.demon.co.uk>
Source record: 36205

Sorry for raising old subject but I've managed to wipe the
answers I saved from last time someone raised the question before I got
round to downloading.

Can anyone recommend a freeware/shareware/limited edition PCB
drafting s/w package with the facility to download the finished product
in a standard format such as jpeg or Paintshop. I don't make many PCBs
but I'd at least like those I do to look neat - even if these days the
bits have to come out of my own junk box.

Thanks,
--
Dick

In article <b71hnr$nr3@unix1.cc.ksu.edu>, mcalhoun@ksu.edu (mcalhoun) writes:

>If switching power supplies do NOT have isolation transformers, do such
>supplies isolate the output(s) from ground?

That depends on the type of switching power supply.

In the newer switching supply buck and boost IC designs using
a minimal parts count, the amount of "isolation" is equivalent to
the lowest breakdown voltage of any component.

"Isolation" transformers of the older variety are basically 1:1
primary to secondary ratios, usually with an electrostatic
shield between windings. Those were intended to remove the
mis-wired AC outlet components between loads that could
have existed. Their frequency of "isolation" is in the audio
range and an electrostatic shield helps keep load transients
out of the input line; that doesn't eliminate it, merely reduces
it. The electrostatic shield reduces capacitive coupling from
line to load but doesn't eliminate it.

>Normal house pole-pigs produce a 120-volt "phase" (not sure if that is
>the correct word) on either side of ground/common. If a house is well-
>wired, both phases may be present at wall outlets in any particular room.
>If one plugs a computer into one phase and another computer into the other
>phase, are their power-supply outputs (including ground or chassis) at the
>(approximate) same potential, or might there be 120 volts difference?

There can be a 208 VAC difference with the common residential
three-wire drop from a utility pole transformer. The higher voltage
service intended for appliances with motors (washers, central air
blowers, etc.). In general, even with 40 year old USA residences
(such as mine) wired to the National Electric Code, 115 VAC three-
contact outlets in a particular room will generally be on the same
"phase" or side of the power drop. That's not an absolute since
this residence has two rooms with outlets split between the two
"phases."

At the time this residence was built (approximately 1962), the
Los Angeles electrical code required metal conduit carrying all
AC power wiring, a separate ground connection for the conduit.
All but one outlet was properly wired according to NEC when I
moved in. I took the time to test ALL outlets then and to make
a little diagram for reference to the numbered circuit breakers
just behind the drop box. Such testers are easy to make, even
easier to buy at do-it-yourself stores. Such basic information on

a residence will come in handy later and can provide at least one item of positive assurance that everything is according to code.

On making half of one room a workshop, I found that there still existed AC potentials between tube-based equipment that had internal transformers. Weak, but feelable potentials between equipment cases. Not comfortable. Easily measured with a hand-held Voltmeter. The cause seemed to be "extra" capacitors in a few, connected between the neutral AC input line and case/chassis physical ground. One one Heathkit, it could have been from the supplied transformer's primary-to-secondary winding coupling. All the equipment was strapped to the same conduit ground, including the soldering iron metal holders and a couple of aluminum plates (added later) that are on the workbench "wiring and building" surface.

None of the potentials between equipments was considered "fatal" since a loading of only 100 KOhms between them dropped the AC potentials to a volt or so. That's a relatively easy task to do with a handheld VOM and is recommended now with a greater use of much-higher-impedance CMOS and FET semiconductors now than four decades ago. Most such semiconductors have built-in ESD protection now but the extra effort reduces the potential negatives on one's wallet. :-)

If you don't know the circuit of the switcher (or can't open the structure to trace it out), just set it up in the same location with load(s) within specified range, and start measuring potentials between it and whatever else you have with a VOM, preferably a DVM with frequency response to the top of the AF range or beyond. You can use a high value loading resistor across the VM if you like...such gives a rough idea of the amount of AC current possible through whatever is the coupling device. Such couplings usually have a rather high "source impedance" so the AC current can be quite small (in the microampere range).

I'd like to have a definitive answer on switching supplies myself. In the approximate two decades of their common use in computers and consumer electronics, there is a wide variety of circuitry and basic architecture. It's not standard, nor does it have to be. It's an evolving thing that will, probably, eventually produce a "standard" arrangement. Not yet. My computer's switching supply (5 years old) is of a different arrangement than my wife's computer PS even though they were system-packaged by the same company a year and a half later. The switching supply box of my ancient Apple][(circa 1980) is quite a bit different in circuit arrangement. The switcher in my Philips 'scope is quite a bit different than all of them.

Bottom line is that you need to define your own "isolation"
needs. Consumer equipment as built already has some
isolation and some specs thereto. You can measure
potentials between your equipment and any switcher with
a VOM or DVM...but probably not from 50 KHz and upward
(which needs a wideband differential-input oscilloscope). If
in doubt, conventional isolation transformers are still available
from Mouser, Digi-Key, Allied, Newark, etc., catalog listings
for both North American and European AC power mains.
If you are worried about HF dribbling out the mains line from
a switcher, add a lowpass filter on that input. Those can
also be purchased...but be careful on the connections of
such a filter.

I think the best for CAD program for homebrew PCB/SCM is CIRCAD.

Download a free version at www.holophase.com

It can save the artwork in BMP format.

Regards Max

Don't know if it's the same circuit, but there's a 6T9 transmitter
in the 1972 handbook that calls for 470V center tapped @ 40 mA,
and 6.3V @ 2A. Based on this, and if you want to buy a
transformer instead of scrounging one, you could use a Hammond
P-T269JX or P-T269EX. They can be had from www.tubesandmore.com
for about $30 (one's a bit high on the B+ voltage, the other's a
bit low, but either should work fine).

Thank y'all for the good advice. Meanwhile I was able to dig up the AB
manuals for the VFD. They also recommend a common mode RFI filter.
After much googling I was able to find one made by Tyco. I ordered
it from Allied Electronics. Hope it works fine. They promise 56dB
suppression @ 150kHz and 70dB up to 30MHz.
Shielding the cables to the motor shall be something like the last
resort.
I guess I would have more difficulty purchasing the big ferrite cores
than purchasing the filter. I'm in Paraguay (ZP...)

Kind regards and thank you again indeed, Eike

There is a free program simply called PCB. URL
:
http://bach.ece.jhu.edu/~haceaton/pcb/pcb-1.6.3/doc.ps/pcb.html

It produces output in Postscript format that can be printed on a transparency,
also will produce Gerber files.

The ferrite core from the deflection yoke of a scrap TV makes a good HF choke (about 10 turns is usually optimum). It's ugly, but it's available everywhere and it's free.

Depends on what you build, but this list is good for QRPers

1. NE602
2. LM386/TDA2822
3. Dual gate MOSFETs
4. FETs (eg MPF102)
5. Transistors (eg 2N2222, 2N3053, 2N4427, etc)
6. PA transistors FET and bipolar (eg IRF510)
7. Toroids (ferrite and iron)
8. Polystyrene or NPO capacitors for VFOs
9. Variable capacitors
10. Trimmer capacitors
11. Vernier reduction drives
12.Crystals (any freq, but esp amateur band)
13. 3.58 MHz ceramic resonators
14. Metal boxes
15. Varactor diodes
16. Germanium diodes
17. 74HC4066
18. Small relays
19. Usual supply of resistors and capacitors
20. PC board material

> After all, doesn't s/he who dies owning the biggest junque box win? :-)

Almost. S/he who gives away the most junk wins ;)

And it's not like options trading - you need to actually have the junk to be
able to give it!

Those are definites.....also, the TDA1572 radio chips are good, along with ceramic filters, crystal filters, mixers, LO crystals, synthesizer chips, and as mentioned in the last post, those NE602s. Those chips make great SSB detectors, along with being ok for mixer service in simple receivers.

You can take your ExpressPCB image, capture it with PrintScreen, paste it into MSPaint and remove the background by hand with the eraser or pencil function

Simple:

Draw $10,999 out of the bank. Use the first $1K to buy a round trip ticket to Tokyo. Convert $9,999 to Yen. Hop the next flight to Tokyo. From Narita, catch the bus to the downtown air terminal. Then the subway to Akhiabara. Buy 3 or 4 of everything you see until you run out of Yen. Use your credit card to FedEx it all home. Return by the reverse route. Have fun.

I've heard that 430s have a problem with bad connections on the PCBs.
Can't remember if it is the plated through holes maybe?
Anyway, it sounds like a connection somewhere is not too solid. See
if there are mounting screws for the boards that could be tightened,
wiggle connectors (take them off and push back on). If this doesn't
work, then take a pencil eraser end and gently push components on the
board feeding the display, looking for where the intermittant
connection is.

>tell me where I might find a kit or something?

Go on ebay, search for "audio amp" or LM386 or LM380.
You will find a guy selling a kit of something like 10 ICs and 1200
surface mount parts, for around $8-10. He is in there all the time,
must have a large supply of parts.
I just put together an LM380 audio amp yesterday, dead bug style on a
PCB, works great. I'm going to mount it in my Drake R4C to lower the
heat, and current drawn by the archaic audio amp in it.

Don't forget, you can always capture an image (of a meter which you like) using PrtScr (saves to clipboard), open it up in MSPaint using "Edit" the "Paste" and play with the image there, saving it as a bitmap file. I did this with a Keithley Meter I liked.

Reasonable userfriendly.
The Postscript files are messy for very fine SMD work (0.65 mm and finer).
Might be fine for coarser resolutions

Imagine a house where the original two-wire outlets had been
replaced by grounded outlets, where the ground screw was simply
jumpered to the "natural" wire. Imagine also that polarity had not
been well observed between fusebox and outlets so that sometimes the
"natural" wire was hot.

BTDT.

Any I should push the Linux solution, Geda Gschem. Debian and Redhat packages
available. This one also has a nice utility for making your own parts libaries
for parts not included in the one supplied. If you download this one you will
notice there are also some tube symbols in there for an AA5 tube set. I contributed
those.

As I kid I used to ride my bicycle around Brooklyn on trash days with a pair of Dyke and gas plyers plus a few screwdrivers in my pockets looking for junker
tv's thrown out. I would carry the chassis home, or just yank out the more valuable
parts. I had to bring along a good shopping bag to carry on the handle bars, it got
filled with tubes, the rest of the junk in a box strapped to the rear fender.

Here is the way it should be done (see URL below). However I don't know
of a source for the coils, because just about all of these circuits are
no longer used, having been replaced with digital circuits such as T1,
etc. On second thought, the coils may be available for radio stations
which use a phone line for their studio to transmitter link. I'm
xposting to 3 other ngs to see if anyone there might know.

2745. Re: Series diodes -- equalizing needed?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-11 03:58:15 UTC
From: fmmck@aol.com
Message-ID: <20030410235815.28272.00000399@mb-ft.aol.com>
Source record: 36148

<< Actually, the equalizing resistors is still a good idea, and still very much needed with the 1N400X series. All ratings are going to vary a bit, and vary even more if you mix manufactures of the diodes within your stack. I have never ran the equalizing capacitors, as they seem to cause problems more often than curing them, >>

Gudmundur-

Please forgive my saying this, but your statement is nonsense. I do not believe equalizing resistors are a good idea. In fact, many resistors that may have been used in such an application were themselves rated at a lower voltage (dielectric, not power) than the diodes they were across.

Consider a slowly rising reverse voltage. As soon as the lowest-voltage diode reaches its breakdown voltage, that diode's increase stops until the highest-voltage diode has reached its breakdown voltage. At that point you've reached the limit and damage can occur. Before that point, power dissipation in any one diode is limited by the leakage current. Since some diodes may have higher-than-rated reverse breakdown voltages, the total voltage can be higher than expected when the limit is reached.

Now, consider a fast-rising transient reverse voltage. It will immediately divide among the diodes in inverse proportion to each diode's capacitance. There is a good chance that some diode will reach its reverse limit long before the others. However, its current is not just leakage, but is now determined by the capacitive reactance of the series diodes. If the diode is not able to withstand the resulting energy pulse, it will fail. With a diode's failure, the voltage across each remaining good diode is increased, and a cascade failure of all diodes might occur.

This is my case for equalizing capacitors. A high voltage ceramic capacitor bridging each diode will prevent any one diode from reaching its reverse limit until the total rated voltage has been reached. What size capacitor? I would consider using the largest practical value that would not result in wasted power or self-heating at the power frequency (eg. 20, 50, 60, 400 Hz).

For a switching power supply with a somewhat higher frequency, extra capacitance might easily upset operation of the circuit. I think it would be better in that case, to pay a little extra and use the highest voltage diodes available to start with, and then carefully take any equalizing capacitors into account in the switching circuit's design.

The 55 suffix probably means that it has been screened for a customer. I would give them a call at 800 654-7949, and ask for one of their application engineers. Feel free to use me for a reference; I know those folks pretty well.
Just tell them, the fellow who used to work for Collins, and they will know who you talking about.

Source record: 36153

I modified a couple of PC PSs per the vk4ba
web page to see if it worked as advertised.
So far, so good. 13.8V regulated on the 10A rectifier.
I see how to move the 13.8V ckt to the 40A rectifier.

No luck so far moving the V/I protection from the 5V line
to the 13.8V line, if this is the right way to say it?

Each PS is different in this regard and I don't find
a straitforward way to do this.

I found I could disable the -5V OK but not the -12V line.
-12V appears to bias two bipolars that work with the LM339
to drive pin4 of the controller chip from near 0 to 4V in
case of a fault. Not clear how to change this to sense
faults on the 13.8V line. The web page treats this for
specific PS models but none I have.
I don't mind digging in when I have a workable mod but
no point when I don't know what I'm doing :)

Perhaps someone has found a straitforward way to do this
that fits most or maybe even all PSs?
TIA John

Phantom circuits and repeat coils are wonderfully fun things to
play with. They make a lot of sense if you have a pair of
leased lines and need one more. Or if you own the cable and
would have to install a new 25 pair cable for a few miles.

Repeat coils are actually very commonly available, except they
will be called "hybrid transformer" instead, and they'll be much
smaller than the coils discussed in the URL (which were designed
in the 1930's).

But between rooms? Running more cable is a *lot* less expensive
and less trouble than trying to multiplex multiple channels.
And if you do have an application where the distance is great
enough to be worth the effort, digital multiplexing would be
much preferred.

John, this is not as good as the one you mention, but it worked, despite the said noise.
First you remove the +5V reference, tracing backwards from the output until you find a small inductor or jumper (remove this). Then you derive the +5V from the +13.8V line, putting a 8.2V zener (stripe to the 12V side), then a regular diode to the +5V. in paralell with the diodes, a 100u electrolitic cap with the - to the +5V.

I did not test this when TX, but the page I saw claims that it works FB to power his repeater for 7 hr, then thermal shutdown...

> usenet@@@@jasonhsu.com

The first stuff you need is more mundane, and more important, because you'll use it in almost every project. 1) Hook up wire. 2) PC or perf boards. 3) You need to add lockwashers to your item #29 (6-32 hardware)

Next in order should be the makings of simple powers supplies for projects - Transformers/wallwarts, bridge rectifiers - and you already mentioned linear regulator chips.

After that, trash most of the list, until you know where your interest takes you. Meanwhile scrounge stuff out of electronic items that get thrown out. People leave TV's, VCR's, microwave ovens, etc. at the curb. Take the useable parts - line cords, hardware, switches, components, motors, etc.

Try a web search for "cohn crystal filter" or even just "cohn filter".
You should get many hits. I know that a lot of them may talk about
building a filter for a specific frequency, but you should be able to
move it to a different frequency by following the recipes/instructions
that many of the articles give. I believe you can also find helpful
software at http://www.aade.com/filter.htm. You can download it for
evaluation, and it is inexpensive to buy. There are articles, too, on
simple crystal tester circuits to help sort the crystals.

Cheers,
Tom

I have 6 SN76514 mixer IC's that are made my TI. I bought
them from Rochester Electronics about 1 yr ago. I used a
couple to repair an older Icom radio. $35 to usa.

Doug, N4IJ

2763. NEW Heath SB-200 plate transformer, $75.00 shipped conus

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-12 05:21:25 UTC

This is an export transformer - so the voltages are going to be higher than what you want for your SB-200 but would be excellent for homebrew single 3-500 or similar. I think the primary is for 100vac. Cleaning shack.

If you can use the J310 which is about the same but in a plastic package youcan fine them on e-bay with a buy it now price. I also saw the U version there. Unless you need $ 20 or $ 30 worth of them or the minimum order from some place , it might be beter to get them off e-bay in bunches of 20 or 30 pieces for under $ 10.

I don't buy anything unless it's something specific I need. I butcher parts from broken down old junk. I have loads and loads of broken down junk. I have loads of much stuff that works, but I never used. About the only parts I ever buy are semiconductors that I can't find in my vast collection of junk. And I only buy what I need at the time. We have local stores here that stock all that stuff, so there is no need for me to. Most all resisters, caps, etc, I pull off circuit boards from broken junk. IE: As an example, I had to dig up a small electrolytic to fix a monitor a while back. Where did I get it? From another broken monitor...I'll throw all these boards in a box, and when I need a part, I just pull them out and look for it. When I find it, I unsolder it and use it. I guess I could unsolder them all ahead of time and organize them, but I don't have time for such time consuming organized sillyness.. :/ I do have a bunch of plastic cabinets with lots of the parts you mention, but I aquired them from someone else who was more organized than I. They were already pre-stocked when I got them. MK

2767. Audio phase-shift network

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-12 09:58:08 UTC
From: jgboyles@aol.com
Message-ID: <20030412055808.00683.00000927@mb-ch.aol.com>

Hi, Anyone have the basic circuitry for an audio phase-shift network for use in a phasing type SSB exciter. What I am interested in is the old B&W Model 350 2Q4. I have the circuits for the modern phase-shift networks, but I have never seen the layout for the older (1950's) networks. The 2Q4 has been briefly discussed here, it is a passive network, wondering if it would be an easier to use.

<< I know this was the usual practice when 'top hat' type SI rectifiers were used. Many years ago I built a linear supply using 1N4007's and I did parallel each diode with a 470k 1/2 wat resistor and a .001 1000v disk capacitor. I don't know if this was necessary or not, but the supply worked just fine. I also used twice as many diodes as necessary (the transformer
was about 2800-0-2800 and I used 10 diodes in each leg of the fw rectifier). The filter cap used ten 330uf 450v caps in series. >>

Scharkalvin-

If I figured it right, your 2800 VAC has a maximum value of 3959 volts. If the capacitor is charged to that value, the peak reverse voltage on the diode string is twice the maximum, or 7918 volts. Your ten diodes do provide a safety margin, but maybe not twice.

Does anyone know the voltage rating of a half watt resistor? I seem to remember a value of somewhere around 350 volts. I recall that for high value resistors, the voltage rating is reached long before the power rating!

Jensen doesn't seem to sell any appropriate hybrid transformers. Or
at least there are not listed on their web page.

Here are examples of the type of transformer required,

Has anyone got a datasheet for the obselete Plessey SP9131.

It appears to be a dual divide by 2 device. I am interested in the signal level it needs at various frequencies. It's part of a VCO in a PMR rig which I am changing to work on 4m. As I sweep a voltage to tune the VCO the signal strength varies enough to not drive this chip for all the range. It's an interesting design to have the VCO work at 2x frequency and then divide by 2, but I have no idea what benefit this brings.

regards...

Gary,

It's a Dual, 520MHz, ECL D type flip flop.

Input needs to swing -0.31 to -1.11V (with a -0.71V bias).

Output will be 600mV p-p.

CLK1 pin 6, Q1 pin 2, /Q1 pin 3
CLK2 pin 11, Q2 pin 15, /Q2 pin 14

Also see MC10131.

Mark.

Nano is half way inbetween micro and pico: 10^-9.

So 1000 pF is 1 nF, and 1000 nF is 1 uF.

In other words you 10n capacitor is 0.01 uF or probably marked 103, 10
with three zeros worth of pico Farads.

Hi,

What reccomendations do you have for a replacement 120 VAC muffin 4 inch fan (3.75 inch center to center mounting holes) for my Clipperton L amp?

I seek something that is quiet!

Please reply by email.

Thanks, Bob

Source record: 36192

I've just uploaded a new version of Dial.zip (the Windows version of Dial) to my QSLMaker site at http://hfradio.org/wb8rcr. I haven't updated the web site yet to indicate the news version, nor have I updated the command line version for Linux nor the Panel program. The Dial and Panel programs are hidden in a link at the bottom of the navbar at the QSLMaker site.

The only change is to allow the dial to be rotated. Previously, the program assumed that the control was positioned "normally", that is, with the dead portion of the control centered on straight down. This is still the default but you may now rotate the dial in one degree increments.

For those of you who haven't used Dial, it is a Windows program that allows you to easily print a dial for a control. The Panel program allows you to create an entire panel, but it produces PostScript output so it's messier to use than Dial which uses whatever Windows printer you have selected.

Say you have a meter that shows position of a variable capacitor in a remote atu.

What would be reasonable accuracy of your meter, I mean, would it be reasonable for the meter to show true shaft position within 1 degree, or is that unnecessarily accurate? What would be reasonable accuracy? TIA. Rich.

U310 is listed in the Tandy Tech America catalog as Cat. # 900-5494.
My catalog is a couple of years old, so they may no longer stock the
device.

If they don't have them, I have a couple of U310s that I might be able
to spare.

2795. 6L6 vs 1614

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-13 23:20:53 UTC
From: Bob P <kb8tl@yahooDOT.com>
Message-ID: <ohmma.18$qa5.37493@newssvr28.news.prodigy.com>
Source record: 36048

I'm using a 6L6 in a recently completed homebrew tx and was wondering if anyone knows what the max grid current is rated at. Receiving tube books don't rate such on the 6L6 but it's transmitting doppelganger, the 1614, is rated at 5 mA maximum. Presumably, I can run a 6L6 (metal) at 5 mA and maybe a tad more into a US made 6L6GB or GC...??????

Rig is SS VFO, heterodyned with crystal osc driving 6CL6 to 6L6 out. about 30 Watts out with 42 plate input, 5 mA drive, 520 V on the 6L6 plate.

2796. opportunistic junk-boxing Re: What parts do you stock up on?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-13 23:30:23 UTC
From: rmonagha@engr.smu.edu
Message-ID: <b7crufkjf1@blaze.seas.smu.edu>
Source record: 36049

agreed ;-) the case and power supply are usually the biggest cost items in most projects, and the easiest to recycle and reuse. The chances of finding specialty ICs and being able to recycle them is getting harder and harder due to surface mounting of computer and electronics parts ;-(

But I suggest that "stocking up" by buying a series of particular parts, (esp. at Radio Shack prices) is NOT the way to go for building a low cost junque box ;-) For example, the 2N2222 transistors are readily substituted in many applications using devices recycled from a board of discrete stuff

Opportunistic junk box feeding takes advantage of very low cost items that can be readily used in general projects (e.g., power supplies) or for specific projects (e.g., longwire antenna tuner) when you find them very cheaply.

I'm looking forward to the ham-com fest in June in Dallas, but meanwhile I stock up at our local monthly computer-fest (formerly hamfest, see http://people.smu.edu/arc/sidewalk.html). If you don't have ready access to such parts buy sources, consider adding a parts exchange before local ham club meetings or via local repeater invitation (e.g., monthly, quarterly, etc.). That's how our local electronics fest got started!...

my homebrew buys tend to breakdown as:

a) power supplies and project boxes (often with something in them) - often ugly (e.g., RTTY p/s with multiple logic voltages at many amps $1 ;-)

b) hard to find items - e.g., I just picked up a boxful of 10 high voltage variable caps of various types and roller inductor coils; last month it was a high voltage xmfr ($1) and 330 mfd 450 vdc caps ($.25). At some point, I'll need these for longwire tuner(s) and high voltage power supply (likely to be a photo studio strobe power supply actually)...

c) test gear, such as digital panel meters with internal 110 vac supplies; often test gear is much cheaper used or to fix than to build new (e.g., old heathkits), including probes etc.

d) stuff that is cheap enough to be worth speculating on, e.g., 2 stepper motors with chips interfaced for $.50 each new in box (for a rotating panoramic camera project); two 2x16 LCD displays with serial chip drivers for $.50 (a morse code decoder?) etc.

I agree with other posters that if you get a lot of stuff for free, that's hard to argue with, but it may be hard to find much you can use or recycle in most computer gear, for example, where custom ASICs and surface mount stuff are problematic. Similarly, your time is worth $$ too - you can spend it building power supplies, or recyle cheap power supplies and focus

your time and efforts on the guts of the project ;-)

Hi Rich,
The shaft position accuracy will be highly dependent on the type of transducer used to provide the shaft position information. A shaft position encoder with a digital readout is capable of 1 degree resolution. With a simple potentiometer coupled to the shaft giving a resistance proportional to shaft position, you could expect maybe 10 degree resolution. With a servo or a synchro rotating the cap, and a calibrated dial at the transmitter end, maybe 10 degrees or less.
These numbers are not absolute, but are roughly based on my experience with various transducers. If you need a true Engineering Specification, consult data sheets on the device you are trying to use.

<< Say you have a meter that shows position of a variable capacitor in a remote atu.

What would be reasonable accuracy of your meter, I mean, would it be reasonable for the meter to show true shaft position within 1 degree, or is that unnecessarily accurate? >>

Rich-

A potentiometer attached to the capacitor shaft could be connected to an ammeter, so that zero degrees produces zero current and 180 degrees produces full scale. I doubt the linearity of the combination, combined with your ability to read one degree out of 180, would be very precise.

If you use an optical shaft encoder for the capacitor shaft, your accuracy will be determined by the encoder. I would think one degree out of 180 would be possible, but what purpose would it serve?

Assuming the ATU is associated with a transmitter, a more meaningful measurement would be reflected power. I don't think it matters much where the capacitor is set, as long as reflected power is optimized. If a meter is used to indicate the capacitor's setting, it would only be of value to show if there is a radical discrepancy. In that situation, accuracy may not be critical.

The 807, yet another flavor of 6L6, whose specs may be found at
http://www.retrovox.com.au/STC807.pdf , also shows a maximum grid current of
5mA in class C. The 1957 Handbook, pp 176-178, shows a 75W transmitter that
runs two 6L6GBs in parallel with 400V on the plates and 200V on the screens,
and recommends a grid current for both tubes of 6mA. The meter is scaled to
read 20mA full scale.

Beware that the 6L6GC is a different tube than the other members of the family.
It can take higher screen voltage and current, and probably higher grid current.

The 6L6, 6L6G, 6L6GA and 6L6GB are all the same tubes except for the envelope. The "G" is an ST16 bulb, the GA is an ST14, the GB is a T14 bulb as is the GC.

The 5881 is similar to the GB with a shorter bulb, brown base, and maybe slightly lower plate ratings. The Metal tubes can not handle more than 450 volts on the plate without danger of arc over to the metal bulb.

I made a new scale for a panel meter used on a VTVM. I photo copied the original
(which was very yellowed) and used liquid paper to white out the original numbers. I then used a pencil to draw in my new calibration markings. I photo copied
the marked up copy (adjusting the darkness as required) to get a good clean new scale.

The original markings were for a 3,10,30,100,300,1000 sequence of ranges. My new markings were for 1.5,5,15,50,150,500,1500 sequence of ranges. I changed the
input divider to match.

That technique works even better if you can scan the original scale, and then use PhotoShop, PaintShop Pro or similar software to retouch the image, delete old markings and add new ones.

The alternative is to measure-up the original scale and then use either Jim Tonne's program to draw a new one for you, or do it from scratch using AutoCAD or AutoSketch (which will produce very good results but will probably teach you more about those programs than you ever wanted to know).

Print on thin, glossy white paper, and use 3M spray adhesive to mount the new scale on the rear of the original plate - if you use the front, the original calibration may show through.

The results will be as professional-looking as you care to make them.

re: Icom PCR1000 garbled audio problem (narrow band fm mode)
-
Hello there,
-
Just a quick bit of feedback... Last week I posted a garbled audio
problem with an Icom PCR1000 receiver.
-
I traced the problem to the Bonito Software supplied with the unit. The
fix is to down load the latest Icom software from their web site and use
it. The Bonito software seems to have a bug or two... it appears to me
the bandwidth filtering doesn't appear to switch properly.
-
I'm happy with the preformance of the Icom software, it would be neat to
have the Bonito Software work, but I'm sure you'll have to purchase and
upgrade to get things on the road as expected.
-
The 200mW audio from the receiver is kind of puny, but it works and will
drive larger power amplifiers/circuits.
-
OK, that's about it...
cheers
skipp

I've occasionally run into projects in books (even ARRL Handbooks)
where the diode rating in a FW supply was underspecified, e.g. 600V
diodes on a 250V-0-250V transformer. I'd guess that sometimes people
forgot that the entire secondary voltage is across the non-conducting
diodes, not just 1/2 the secondary voltage. (I'm not suggesting this
is the case in Scharkalvin's case, where he did have enough
reverse-voltage margin)
>

I believe it's 350V for 1/2W, 500V for 1W and 750V for 2W. Wonder how
many projects made *that* mistake!

It varies between different types, but those are good guide values.

>Wonder how many projects made *that* mistake!

Lots! If you specify resistors that will stand 1000V, you'll find they
cost much more than the diodes they're intended to protect.

There's also a problem for equalizing capacitors, but this time it's
about tolerance. Typical high-voltage disc ceramics are specified at
+/-20%, which will quite effectively UN-equalize the reverse voltages!
If you specify high-voltage capacitors with a tolerance of only a few
percent, you'll again find that "cost inversion".

It's more cost-effective to use larger numbers of new, full-spec diodes
without either resistors or capacitors.

Hi Serge,
Way back in about 1957 I went to a club meeting in West Hartford, CT, home of the ARRL then, and Ed Tilton, of the ARRL, was the speaker. He showed a 2m phasing exciter he had built in which he used a length of coax for phasing the RF signal. Since the freq. only changed a very small percentage when QSY-ing, the phase changed an insignificant amount, and didn't need to be adjusted. It was only half wave, shortened by the velocity factor, and it was looped inside the chassis. It was a trick that impressed my teenage mind and has stuck with me. I don't know if that unit was ever published.

Hi all,

I am trying to build a simple Z80 circuit with a 2k EPROM (2716) and a 2k SRAM (6116) and am trying to remember the best way of handling the chip selects. I seem to remember something about slow EPROMS causing a problem?

I have a schematic at http://sholtz.port5.com/z80.html which I think is correct and should give me a ROM range of 0000h - 07ffh and a RAM range of 0800h - 0FFFh. But I would be pleased if anyone has any better suggestions/advice...

You have it nearly, but not quite, correct. I believe that the circuit was published in either the G.E. or RCA ham pamphlets which were like small (4- or 8-page) magazines, published periodically. I cannot remember the names of those publications, except that the one that G.E. put out featured "Lighthouse Larry," a cartoon character based on the 2C40 lighthouse tube.

Anyway, back to the circuit. It used a 1/8 wavelength coax line and a 3/8 wavelength coax line to produce quadrature rf signals which were directed to a double balanced modulator. The quadrature audio signals for the modulator were the outputs from an audio phasing network enclosed in a metal tube housing (same size as a 6C5) and made by B&W (I think - my memory leaves a lot to be desired). Anyway, I built up the circuit and incorporated it into a transmitter ending up with a

3C29 final. The VFO was a BC-221, but I do not remember the intervening circuits. I used this rig on 2M SSB for several years.

A lot of years ago, especially for someone trying to remember things that have happened in a ham career that started in 1939.

It was in QST in 1964, though I can't provide the month.

When I saw the subject header, I immediately thought of that article.

Now that you mention it, I think it did refer to a previous article
in one of those manufacturer's newsletters.

The scheme of using wavelengths of coax for the phasing network
also showed up in the RSGB VHF manual in the mid-seventies (and I
would suspect other of their publications), and though I'm not going
to look it up, I think they had a transistorized version alongside
a tube one.

Realistically, it's the coax phasing lines that are important. I'm
not sure there is a lot of reason to duplicate the rest of the old
circuitry, when others have shown phasing circuitry, using more
recent components. There's no sense tracking down a B&W 2Q4
audio phasing network when it's now far easier to get precision
components.

The one in QST was doing the modulating at a low level, with the
expectation of amplifying it afterwards. But once you've got phasing
on the signal frequency, one could also go to high level balanced
modulators, doing away with the need for linears. This was
seen from time to time in the old days, but now when phasing
transmitters come up, nobody seems to be talking about high level
balanced modulators.

> Rich.

The capacitor position as viewed by the person using the
ATU is only to get in the ball park. Once in the ball park,
you tune by watching instrumentation, not the physical
position indication of the cap, so I would say that 1%
accuracy is tremendous overkill.

I just looked at my manual ATU. There are 20 "tick marks"
for 180 degrees capacitor rotation. Every other tick is
numbered. When I tune, I put it on a number, then tweak,
watching the SWR meter. Based on that, reasonable meter
accuracy would be 9 degrees - i.e. within 1 tick mark.

What is your clock frequency and what speed is the EPROM - you might need
one or more wait states? The RAM will be OK.

I built something like that over 20 years ago, with a simple
monitor/debugger.

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday April 20th 2003
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

I dug up the QST article, it's the November 1964 issue, on page 11,
"Balanced Modulators for VHF and UHF Sideband" by James O'Hern
and Thomas Sly.

It references the GE Ham News article, "A 144Mc Direct SSB Generator"
by O'Hern, in the Sept-Oct 1962 issue.

There's enough in the article to get it going, but the prime reason
for the QST article is to update the balanced modulator. He starts
off by saying people were having problems finding four matched triodes
used in the original, and there were layout problems, which resulted
in less than ideal balance.

They switched to two dual-triodes, 2C51's, because their pinout
was more conducive to a balanced layout. (And it's the only time I
can remember seeing a 2C51 used in hobby circles.)

It also shows a transitron oscillator, again the only time I saw
it used in a practical hobby circuit, for it's apparent stability.

"As in the Ham News unit, the balanced modulators are driven from
a 50-ohm source, split by a coaxial-line T arrangement. One branch
of the T is 1/8 wavelength of RG-62/U and feeds one of the dual triodes.

The other branch is 3/8 wavelength of the same type of cable which feeds the second dual triode. For 2 meters, the lengths figure out to be 9 and 27 inches. This arrangement gives a very accurate 90-degree RF phase shift over a wide band of frequencies. By using terminated sections, instead of a single quarter-wave line, the RF amplitudes at the output ends of the T are equal and the VSWR is low."

As I said, the coax phasing line is the key to all this, and could be used at other frequencies up until the lengths of coax get too big, or too small, to deal with.

And once the scheme is understood, there is nothing to prevent it from being used with more recent balanced modulators, including the T2. The QST article mentions how they tried diode balanced modulators, with less than ideal success, but then that was nearly forty years ago.

While on the subject of coax length vs frequency, I am reminded of a 1-megawatt Loran amplifier I worked on at Federal Telephone & Radio in the late forties. It was for the original Loran frequencies, 1800-2000 Kc (this was before kHz!). We used a half-wave coax balun to convert the 50-ohm unbalanced 160 kW output from the driver transmitter to the push-pull amplifier tubes - actually 12 in p-p-parallel. The coax was RG-8/U or RG-213/U wound in a flat spiral on the back wall of the amplifier cabinet. At the center frequency of 1900 Kc, this would have been about 176 feet.

You are absolutely right Lou. If someone is not interested in the FA items they could easily add them to a kill filter and they would never be bothered by them. As for myself, I don't mind them. I glance at the title to see if it might be of interest to me and then go on. The problem is that a lot of people want control. If everyone had it exactly their way, there would be no posts.

2836. Cutting PC board material

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-15 22:59:47 UTC
From: Bob Liesenfeld <wb0poq@visi.com>
Message-ID: <3E9C8EE3.26324F8@visi.com>
Source record: 36092

Hi gang,
I have several large (15"X15") pieces of PC board that I want to cut up into something like 4"X2" strips for some 'dead bug' projects. I have been struggling with tin snips, but on pieces this big, they just don't cut it (sorry).

Any thoughts on cutting this stuff? I would just as soon cut off individual pieces as opposed to cutting it all up at once.

Tnx es 72

MFJ made two antenna analyzers. One was the "simple noise bridge" and
almost next to useless. The other one had the signal source and was rather
complex. It worked very well for what it is.

Almost any 2716, 2516, or even 2532 should be plenty fast enough. The only instance where I ever ran into timing issues was with the ancient dinosaurs like 2708, or 1702. Those 2 chips were tri-voltage, and make great pistol targets for 25 yards.

use a steel rule as a guide and score the pcb on both sides with a sharp stanley type knife. then just snap it.it either doesnt snap so score it again, or it gives a lovely straight "cut". works with all pcb up to 1/16 inch, including fibreglass..

Excuse me? rec.radio.amateur.homebrew is a discussion newsgroup.
You want ads here? Then don't expect us to answer your messages.
Indeed, don't expect us to fill the newsgroup with content if
you think the lack of ads will result in "no posts".

There is a newsgroup, rec.radio.swap for you to sell your stuff.
We aren't people "who have no idea what is going on" we are people
who have been around this newsgroup for years. I've been here for
8 years, I'm pretty sure some still around who have been here for
longer. Back then, there was even fuss about personal forsale
ads generally, because it was still on the cusp of the internet moving to
a more commercial medium. People like you use the excuse "well
the charter doesn't say anything against ads", when the fact of
the matter is that when the newsgroup was created, it did not need
to be specifically spelled out in each newsgroup charter because
it was the norm, with the exception being specific buy and sell
newsgroups.

So when people complain about your ads (and this particular one
has been made a lot worse by the cross-posting, and the frequency of the
same ad) it's because we do know that they are out of place. And given
all that we have put into the newsgroup over the years, in
terms of posting discussion, I think we have a little bit more
to say on the matter than you, a relative newcomer.

Letting ads in is dangerous, because as I've said so many times,
once there are even a few ads it in effect gives permission to
others to post their ads. And it doesn't even stop with items
related to the newsgroup; first you get ham equipment, then you
get the consumer electronic stuff, then the computer stuff, and
then the guns. And then since there's already junk and off topic
at that, it's easy to slip in completely off topic discussions.

Witness rec.radio.amateur.equipment It's not a forsale newsgroup,
despite all the ads. It's for discussion of the equipment. People

years ago were brow-beaten when they tried to keep the ads out,
so it slid even further.

Witness rec.radio.amateur.boatanchors I remember when it was
created, and there was an argument over whether the charter
should allow ads. The people who felt that buying and selling
was integral to the hobby won out. It didn't take long before
the ads were more numerous than the actual discussion. And I've
seen all the ads for things that aren't boatanchors; idiots think
that their need to sell something overrides what others think
so when they see ads in that newsgroup, they throw in theirs
for everything else, including recent amateur equipment.

Witness rec.radio.amateur.misc It's not particularly full of ads,
yet what's the point of it when there is virtually nothing in there
of value.

I'm tired of people like you trying to bully people who want these
spaces to still be a good place for discussion, by using terms like
'net cop" and "control freaks". I've seen people give up on that
task, and I regret that, not just because they shouldn't have been
bullied, but because by not making a stand, it just gets that much
easier for the ads to show up.

I want to buy some electronic components for building robotics related stuff. I don't know where to buy the parts like diodes, ICs, transistors, resistors ,capacitors, connectors etc. I saw some parts in Radio shack, but the selection is very limited and pricey then most other mail order stores. I am reluctant to mail order stuff since I need in small quantities.

There used to be a active/future components store in Ronkonkoma which had decent selection, but this store is closed recently. So, I am on a lookout for retail store that sells electronics store.

TIA,
Satya

That's how I do it. I scribe it first (with a scriber, of course) as I find
it stops the knife wandering. I use paper/fibreglass composite PCB material
(FPC-16) which cuts and drills much easier than FR4 and is cheaper.

Evidently you need more practice reading posts. I did not post the
ads. I don't condone the ads. I don't care if the ads are there or
not. I have yet to post an ad to any newsgroup. I've been here longer
than 8 years. Like I said, learn to use a kill filter. I never used
the term control freak or net cop. That term seems to fit you pretty
well though.

Hello All,
can anyone tell what effect using a BIRD Model 4307 (75 Ohm) in a 50 ohm system would have on the readings one gets - I found out tonight (when I peeled back a sticker) that what I had thought was a 50R model was in fact the 75 ohm model 4307.

How much diffence would this make, and would it be frequency dependent, ie as the internal coupling elment approaches the lenght of the frequency being measured?

If you use any power tools to cut PCB material, be sure to wear a dust mask and something to keep the dust out of your eyes. Wash your hands when done. That fiberglass/epoxy dust is not something you want in your lungs or eyes, and it can make your skin itch.

Hi,

I've seen some hand-held devices that claim to be able to display what the part is and its pin-outs simply by connecting it up any way around to the device's test probes. Has anyone here got one? I'm fed up with looking up pin-outs and fiddling with DVMs and would be happy to splash out the 60 quid or so most of these testers are priced at. Are they any good? And can they reliably determine the subtler differences between source and drain in all FETs, for example?

======
Being in the same situation like you with quite some PCB cut-offs ,also larger pieces to make project enclosures, I use an electric jig saw , followed by trimming with a circular stone grinding disc placed in a saw bench with cutting guide. This results in nicely straight square or rectangular pieces.
Final finish is with a fine file or abrasive paper.

For simple circuits I use PCB with 4 mm circular islands ,using a special 5 mm 'island drill' . The drill is in fact a small cylinder ,the outside and cutting edge covered with 'diamond grit' ,and fitted onto a 3 mm shank.
The island drill is placed in a small vertical drill stand for cutting any circuit PCB material
This method is very suitable for RF circuits since the islands are insulated from the circuit board earth plane by circular rings less than 1 mm wide.
With a bit of care using very little thin solder ,one 4 mm island can be the connecting point of up to 4 components leads . A pair of adjacent islands drilled at minimum distance can inter-connect up to 6 component leads.
I purchased a few 'island drills' through the QRP-community (G-QRP Club).

I think you are right. Knowing the actual position of the capacitor shaft within a degree is overkill. What is more important is repeatability, ie you set your frequency and tune up, noting the meter position. As long as the meter position and the capacitor shaft position keep the same relationship, next time you want to transmit on the same frequency you should be able to pretty much set correct tune position by just getting the meter to read the same.

I reckon I ought to get rotation accuracy within 5 degrees, so when meter reads 20 (1/5th od 180 degrees) the capacitor shaft will be about 36 degrees +- 2 degrees. More important to get the end stops right, so when meter reads 0 the shaft is at 0 degrees, and when meter is 100, shaft is at 180 degrees. You can probably do that by adjusting preset resistors.

Anything in this sort of idea that can be done with these
coils can be done with cheap op-amps. Using these powered by a
cheap wall-wart can make it feasible for very short runs.

The 160 kW is peak power; Loran is a pulsed mode, although the duty cycle is relatively long compared to most radars. That peak power equates to about 2800 Vpk, well within the breakdown rating of RG-213/U or RG-8/U.

As I recall, the Loran pulse width was 45 ï¿½sec and the highest pulse rate was 33 pps. This equates to a duty cycle of about 0.0015, so that the average power in the coax was about 238 watts (160000*.0015).

I'm sorry, perhaps I should re-word what I previously wrote. I did
not mean to be a "policeman," only to voice my feelings. Try this:

I do not like ads in this group. I'm offended by them. I believe
others are also, as evidenced by what I read here. To me, it's a bit
like going to a library to read quietly, only to find someone loudly
reciting poetry in the middle of the reading room. Based on what the
original poster has been doing, I would say he's running a commercial
enterprise (albeit a small one) building coils, posting them on ebay,
and posting ads here. I urge him to stop that practice of posting his
ads here. If it continues, it may drive me and others away from this
group. I'm sorry, but killing things isn't an option for me. Flame
me if you wish for these feelings, but I'd ask, which is worth more to
this group, postings from bright and helpful folk like Wes Stewart,
or "FA" ads?

There are appropriate places for "FA" ads, but I happen to believe
this isn't one of them, any more than the reading room at the library
is an appropriate place for someone to be loud.

Cheers,
Tom

> 73,
> Al, W8UT

Al,

sounds very similar to a design that used to be published in the RSGB
VHF/UHF Manual.

IN that design, it used two lengths of coax (1/8 and 3/8 I think), to
provide the two RF signals separated by a 1/4 lambda delay line.

I remember speaking to someone that had tried reproducing the design,
but with very poor results.

> the frequency being measured?

If the meter is calibrated properly to measure in a 75 ohm system,
then the readings you get will be relative to that 75 ohms. So if the
load is a 50 ohm line that happens to present a 75 ohm load where the
meter is connected (1:1.5 SWR in the _50_ ohm system), it will show no
reflected power on the meter. On the other hand, if the SWR in that
50 ohm system is 1:1, the 75 ohm meter will show a 1.5:1 SWR.
Unfortunately, it would also indicate a 1.5:1 SWR with a 112.5 ohm
resistive load, which would be 2.25:1 SWR in the 50 ohm system. So an
indicated 1.5:1 SWR could be anything between matched and 2.25:1 SWR
in the 50 ohm system it's hooked to. The meter can only respond to
the load which is connected to it; it knows nothing of the actual SWR
in the line it's connected to, since it doesn't know what the
impedance of that line is. If the meter indicated phase as well as
magnitude, you could use that info to find the SWR relative to any Zo
impedance you want, but I guess you only have magnitude available.
(All this could of course be re-worded in terms of indicated forward
and reflected power instead of SWR.)

If the meter isn't properly calibrated to measure in a 75 ohm system,
then you don't even have as much info as I suggested above...

Cheers,
Tom

My sentiments exactly. Well said.

1) I don't have the ability to "kill" posts and even I did, if I killed every poster that I disagreed with at one time or another I would be reading a blank screen.

2) The posts in question probably violate the poster's ISP's TOS.

3) The posts made to look as if I originated them (along with the ineffective attempt to disguise the origin) most certainly violate the TOS of that child's ISP. When he gets booted off, I hope his daddy gives him a good spanking.

If you want to call me a cop, so be it. If you want to put me in your "kill file", your loss, not mine.

2867. AD9854 DDS "wobble" question

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-16 19:35:21 UTC
From: Jan Wagner <jwagner@cc.hut.fi>
Message-ID: <b7kbhf$7o9$1@nyytiset.pp.htv.fi>
Source record: 36119

Hi,

I've a AD9854 DDS running, but the output is very "wobbly" even after filtering. It runs at 200MHz (50MHz x 4). Low pass filtering at 50 MHz with a 3-pole C-LC. Even a 1 MHz DDS output the signal is very messy, with low frequency "wobble" content. Here are two scope traces to show what I mean:

http://www.hut.fi/~jwagner/electr/dc-rx/scope/dds-1470kHz-wobble-1.gif
http://www.hut.fi/~jwagner/electr/dc-rx/scope/dds-1470khz-wobble-2.gif
(the grey area is the afterglow you'd see on a CRT scope)

As the scope pics show, at 1.470 MHz the max phase noise (or, jitter...) is about 20ns peak-to-peak. Really horrible... The cheap 50MHz reference xtal oscillator which clocks the DDS is rock solid compared to these 20ns of jitter.

Shouldn't the DDS output show much less phase noise??

Esp. as the DDS reference clock jitter gets divided down into the output (t.ex. 50MHz=>1.47, 34:1 jitter reduction)?

Or is the 10nF 1.3kOhm PLL filter recommended in the AD9854 not "good enough"? I tried a poly cap + standard resistor combination, and later a chip cap + smd resistor, same result. Btw, analog and digital supply rails on the chip show <<20mV ripple or mess, so a bad layout or supply RF decoupling probably isn't be the problem here...

And - if someone has tried - is the output less jittery if directly clocking the AD9854 from t.ex. a 200MHz low-jitter SAW oscillator?

puzzled why it works so lousily...

- Jan

>
>
>Anything in this sort of idea that can be done with these
>coils can be done with cheap op-amps. Using these powered by a
>cheap wall-wart can make it feasible for very short runs.

That would be a *bad* mistake! The hybrid transformers are
nice, never fail, passive devices. Op-amps are active devices
requiring multiple components, all of which raises both the
failure rate and the cost. There is exactly one advantage to
using op-amps, and it would be an overpowering one if
multiplexing were actually necessary. That advantage is
amplitude distortion, where the op-amps are great and the hybrid
transformers are very restricted.

Regardless, between rooms in the same building????

Buy more wire. It is by far the better solution.

I've never used the AD9854, but I can tell you (having designed some

of these things) that Direct Digital Synthesizers in general
inherently suffer from phase noise. Think of how a DDS works:
At each clock pulse, a small phase increment is added to a register.
When the register overflows, that marks one cycle of output. Unless
the ratio of the input clock to the output frequency is an exact
integer number, the number of phase increments (i.e., clock cycles)
per output cycle will vary from one output cycle to another.

So, it's not surprising that you see 20 nsec of jitter with a 50 MHz
clock, since that is exactly one period of your clock.

If you really need low phase noise, you may have to use the DDS
output to drive a phase-locked loop. That's the usual way of cleaning
these things up. Or, if you're free to choose any clock frequency,
you will find that some frequencies (those which are integer
multiples of your output) give a much cleaner output than others.

Good Luck,

-vs-

Hi Fisher,

I imagine that you must have got the NAND circiut from a Zilog ap-note, I designed an SBC around a Z80180 once and this was not needed, although adimitedly I have never worked with 2716s or 6116s. I design SBCs for a living, my work can be seen at http://www.midwestmicro-tek.com any boards that are on that site are my designs. Your design looks ok but personly I would use 32k devices since they are easier to come by than the older '16 devices. 27C256 EPROM and 65256 RAM devices can be gotten from BG Micro for a few dollars each and you would not have to worry about slow access times. Also if you ever decide to move to an eprom emulator, which makes developing programs much faster and easier, they generaly only work for 28 pin EPROM devices (8k, 16k, 32k) and will not work with 24 pin devices. If you are interested in my Z180 design (that worked well and we sold for 8 years) and a design I have for the Z-80 (which I never got around prototypeing) send me an e-mail, I may still have a couple of old CDs with the schematics and the SBC manuals around some where. . . . . .

Hi all.

I'm trying to rebuild an old FM transmitter with tubes, but i don't
have all necessary air-variable capacitor that the circuit needs.
So i think to build some myself from scratch because i found a little
in shops but these capacitors are very expencive.
I would like to build some AVC with 30pf and 50pf capacitance.
I would like to ask you for advice, ideas, or sites URLS with similar
projects.
As i said i haven't all necessary capacitos, the capacitors that i
have , are builded with porcelain.
As these capacitors will be work with RF, is it necessary to build
with porcelain ?
Is it ok to use PVC or similar material instead of porcelain ?

Thank you.

Source record: 36129

Hi

tried a search for intermediate frequency, zwischenfrequenz etc, but
didn't find the basic rules which were important back in the history
for choosing IF. Suppose the previous IF for USA was 465kHz, Denmark
447kHz, Germany 460-470kHz. The frequency was determined to avoid
heterodyne signals between two local transmitter, usually one on
longwave (150-350kHz) and another on medium wave (550-1600kHz)
broadcast bands

any suggestions?

Need the info for my site, see http://home.online.no/~la8ak/16j.htm

Actually 455KHz for most radios in the USA - 262KHz was frequently used in car radios, and more recently I see more 450 and 460KHz units.

We've never had a longwave broadcast band in North America.

FCC regulation 73.182(s) states in part:
"Additionally, in selecting a frequency, [for building a new station - ds] consideration should be given to the fact that occasionally the frequency assignment of two stations in the same area may bear such a relation to the intermediate frequency of some broadcast receivers as to cause "image" interference."

The regulation fails to specify any particular IF frequency though - and says that since such interference can be rectified by changing the receiver's IF (?! - obviously written in the 1930s...) the government won't take it into account when authorizing frequencies. They then, when establishing regulations for FM, *did* take a specific IF (10.7MHz) into account, establishing minimum distances between FM stations 10.6 or 10.8MHz apart. Similar regulations exist for analog TV, recognizing an IF of 41-47MHz.

I suspect 455KHz was chosen as a standard by the Radio Manufacturers Association so that broadcasters could predict what combinations (i.e. 540KHz & 1450KHz) might cause problems and avoid them.

Why in the Multiverse would anyone want to pollute ham frequencies
with something like a baby monitor?

Assuming that doing so would even be legal under Pt. 97...

Actually, the common IF for AM broadcast band home receivers in the USA is 455 kHz., some early automobile radios used 262.5 kHz., FM broadcast band radios universally use 10.7 MHz., a common communications radio IF is 21.4 MHz., the TV broadcast receivers have an IF in the 45 MHz. range, and 70 MHz. is common for some cellphones and TVRO receivers.

Of course, any manufacturer is free to choose an IF of their own desires. I've used some oddballs in my time, but I stick to one of the standards (where parts are cheap) when I can.

If building your own IS an option, take a look at this little
instrument:
http://www.qsl.net/kd1jv/rlb.HTM

I have not built it but it looks interesting and should be pretty
inexpensive to build.

As for keeping the batteries alive in the MFJ259, I keep a plug in the
external power jack when not in use. That disconnects the battery pack
so if the pushbutton gets pushed in it doesn't matter.

Of course, when the issue of slow EPROMs with CPUs came up,
the EPROMs did have slower access time.

Pete Stark once mentioned something about this, in one of
his articles about the SWTP's 6800. I can't remember the
detail, but he suggested leaving one of the pins enabled,
rather than selecting it when needed, which apparently got
rid of some of the delay time. Obviously, it would have to
be the output enable or chip enable. The former does not make
sense, unless the output actually doesn't work unless the
chip is enabled. Maybe this prompts someone to remember exactly
what the scheme was.

Hi.

I'm curious of what manufacturers literature says is the rated voltage of their variable air-spaced capacitors.

If you have some literature on air-spaced capacitors (like Jacksons Bros etc) then would you mind giving me the vane spacing and the rated voltage of the capacitor? In particular, I'm interested in what voltage is given for a 0.8mm (0.08cm or 0.031") spaced variable, but would be interested in wider or narrower spaced capacitors.

Thanks.

Rich.

Ah, I see.

Air Gap (mm) Test Volts (Kv)

0.48 0.75 Peak
0.6 1 Peak
1.2 2 Peak
1.22 2 Peak
2.13 4 Peak
4.55 6.5 Peak

Air Gap (mm) Test volts (kv)

0.91 2
1.27 3
1.62 4
3.25 6

I wonder if the test volts refer to RMS quantity in bottom set of
figures.

On the one hand, it is quite legal to use modified or
built-from-scratch equipment on ham frequencies if you are licensed as
Technician or above.

On the other hand, you are responsible for making certain that there
are no spurious emissions that would interfere with other users or
equipment on any frequency.

Experimentation is part of the hobby.

There ought to be a standard rating for air-spaced capacitors. I'm
guessing that a 1Kv rated capacitor has a flashover voltage of about 2
Kv. Anway if you have 1Kv across the cap. you ought to just buy a 1Kv
rated capacitor.

I would like to connect three radios to ONE amplified speaker. So far as I know it would not be good to simply connect all three
radios audio in parallel, so how can it be done? A mixer ... too expensive.

Can I take a project box and three isolation transformers to do the trick? Browsing through an electronics catalog I saw a
'telephone' transformer which is 600 ohms primary and 600 ohms secondary. It is small and inexpensive. Could three of these be used
to 'mix' all three radio's to one speaker?

Am I on the right track with this or is there another (inexpensive) way?

Thanks,
Vic

Do you want to listen to all the radios at the same time? Seems like you would like to hear only one at a time.
>I would like to connect three radios to ONE amplified speaker

If you wish to hear only a selected radio at a time, get an selector switch (cheap) and feed only one radio to the amp speaker.
>So far as I know it would not be good to simply connect all three
>radios audio in parallel,

Yes, then you would hear all three at once, and possibly damage the output stages of the radios.

>Can I take a project box and three isolation transformers to do the trick?

Just get a selector switch, rotarary or otherwise, preferably one that would terminate the unselected radios in their desired output impedance. If you take 3 isolation transformers and connect them all together to feed an amplified speaker then you will hear all at once.

> Do you want to listen to all the radios at the same time?

Yes ... one is a scanner which would interrupt only occasionally

Plus, I would like the convenience of NOT having to switch every time between radios.

Sorry, you have redifined the problem.
>Yes ... one is a scanner which would interrupt only occasionally
>
>Plus, I would like the convenience of NOT having to switch every time between
>radios.

Well, then you must assign a proirity to each radio, and decide which one gets sent to the amplified speaker when one breaks the squelch. This is not simple or cheap.

Thanks for info.

It is interesting that it is at least an FCC document to quote, so it may seem to be a reason. Wonder if it is CEPT or CCIR documents for this area... But suppose it wasn't so easy to align the IF dependent on where you lived. 465 was standard IF in USA before 1940, and 455kHz seems to be the normal after 1940, as it would be in Europe after 1950 (or 1960).
It seems that some differences may have occured earlier, but when models were exported to one region to another the standard would be normalized to 455kHz.
Seems that Philips used 130kHz for their early radios.

The problem is outlined as follows. If you have two stations in an area, one at 600kHz, the local oscillator is 1055kHz and you can't have another for the same area on this frequency, because of beat tones between the local osc from neighbour receivers and the station you are listening to. LO radiation from broadcast receivers are quite infame.

Suppose the European problem is like, if your local station is on 200kHz, the image frequency is 910kHz above = 1110kHz, suppose it was American Forces Network in Bremerhafen(?) back in the 60's, and BBC2 on 200kHz, two of the most popular stations in North Europe. Some problems may have dissappeared when medium wave stations changed to 9kHz channel distance, seems to be the same for LW since BBC2 moved from 200 to 198kHz

Though, of course, the image will be 2*10.7MHz = 21.4MHz away from the
desired. On the other hand, I'd just as soon not be listening to the
LO of my neighbor's radio instead of to the station I want to receive.
With the density of FM stations in metropolitan areas, I wonder if
that minimum distance rule is followed, though.

Cheers,
Tom

**If you mean the atlas tester, by Peak Instruments, then YES, YES, YES! It is an outstanding bargain for anyone dealing with a wide variety of semis, every day. It is fast and pretty much foolproof. It does have some difficulties with transistors which are diode protected, or those with internal resistors, but it reports that this is the case, so you can make allowances, accordingly.

Highly recommended.

If the signal commons of all the radios can be connected without screwing up the power supplies, then you can make a simple resistive mixer and put the result into a powered speaker like those made for computers. If the grounds must be isolated, than you could add one of those isolation signal transformers in each signal poath before the resistive mixer. But you should amplify to speaker volume after mixing.

Vic,

If you have the speaker output of each radio, just put an eight or four ohm resistor across the speaker output of each radio, tie the ground sides together, assuming that they have a common ground and then put about a 50 ohm resistor from each hot side to the input of your amplified speaker and use the common ground to the ground side of your speaker. The 51 ohm resistors will provide enough isolation to each radio, and you don't even need a power supply.

By who's definition? Op-amps are not difficult to work with, nor
are they particularly expensive. Seems like a few hours of design effort
could do everything you need.

What I'm doing for my van, since I have multiple transceivers and a
scanner, is adapting a surplus aircraft audio panel to the task. It has
several inputs, and is designed to drive either a single speaker or a
couple of headsets. I bought it on Ebay for about $50, and got the manual
for it (which included full schematics) for another $30 or so from the
manufacturer.

You may want to try the same thing. But, as others have pointed
out, the 'priority' scheme you seem to want will not be easy or cheap to
implement.

> A&P, CFI, and other good alphabet soup

455khz (though 456 and 465 were also used) became common when cheap
radios without an
rf stage (AA5's) came into being. Before that 175khz, 230khz, 260khz
were also common, usually
in radios with an rf stage. Since auto radios typically always have an
rf stage a lower IF was common,
hence 262khz. The lower IF yeilds greater selectivity, and since auto
radios often find themselves in
areas with weak signals, or with stations close together in frequency
the combo of an rf stage and
a more selective IF was a good idea.

Strange that the 21.4 if is twice 10.7 mhz (why did that get chosen?)
Also 11.7mhz is a common if in vhf radios, a Standard
2 meter hand held I used to have used that IF.

Leave the chip select enabled and gate the output enable pin with and
and of
the address decode and the read signal. This will net you and extra 10-50ns
of access time advantage.

Don't gate the memsel signal with the read strobe. Combine the address
decode
with the memsel signal. This will also net you a few ns advantage.

Well, I got curious<grin>. I have a reprint of a Supreme Publications book "Most-Often-Needed 1926-1938 Radio Diagrams, Volume One". It contains service information for American radios in this timeframe, including circuit diagrams.

The IFs most often quoted:

456 42
175 30
465 22
460 17
262 12
450, 455, 470 9 ea.
260 7
181.5 5
177.5, 252.5, 2 ea.
472.5, 262.5,
264, 370, 130
448, 485 1 ea.

Of course this covers a lot of time. 175KHz seems to have been used more often in the earlier part of the period. There aren't that many car radios in this book; a lot of the use of frequencies near 262KHz was in home radios.

Unfortunately I don't have any more recent diagrams - I do have a TV book for 1948; one 1948 TV set had a built-in MW radio which used 455KHz.

> It seems that some differences may have occured earlier, but when

I don't see that there was much export of radios to the USA before 1945. Best I can tell all the radios mentioned in this book were made in America.

> problems may have dissappeared when medium wave stations changed to
> 9kHz channel distance, seems to be the same for LW since BBC2 moved
> from 200 to 198kHz

Even if you don't have a LW band, this problem can happen within the MW band as well. Admittedly on only five channel pairs (550/1460, 560/1470, 570/1480, 580/1490, 590/1500) until early 1941 when the top of the band was expanded to 1600KHz here. And of course, we never adopted 9KHz channel spacing.

There is a second potential problem: that of two stations separated in frequency by the IF mixing within the receiver and being demodulated regardless of the setting of the LO. For example, if you had a radio with a 460KHz IF and strong stations on 600 and 1060KHz, they could mix to form a 460KHz signal that could be heard across the entire dial. I suppose the desire to use an IF halfway between two channels would minimize (but not eliminate) this problem. (why 456KHz instead of 455?)

Apparently LO radiation was a serious problem for early television receivers. (many didn't have RF amplifiers, so there was little isolation between the mixer and the antenna) I understand that was in large part the reason the standard TV IF was changed from 21-27MHz to 41-47. (interference from the new 15m ham band being a secondary reason)

Today, I still have some trouble with it on FM. I have relatively exotic tastes in music and am relatively likely to listen to weaker stations in the car. It is not unusual for the station I'm listening to disappear as I pull up to a traffic light. When that happens, I quickly realize it's related to a specific car - and quickly realize there's a strong station 10.6 or 10.8MHz away from the one I'm listening to...

> Bob WB0POQ

Hi Bob:

Getting the boards cut up at a machine shop using a shear is real handy.

I found that the use of a jeweler's saw has been a godsend for small work.
It takes a bit to learn to use one, but the cuts can be small in width.

I also use it for small parts fabrication in copper. aluminum, and silver(hey!).
The blades are more fragile than hacksaw blades. It provides for much greater control over a hacksaw or Jig saw.

Cutting being performed on the pull or down stroke. Like a Japanese saw.

For routing out slots or separations, I use Vanadium steel dental burs in my Dremel, works great for separations of pads for "Dead Bug" fabrication.

Best regards
Clark Southoff

Hi Eniac,
look at http://hamradio.online.ru/cap2.htm The variable capacitor has a semi-cylindrical shape of electrodes. IMHO, its construction can be simplified even more, if one makes the rotor from a glass tube with copper or aluminum foil glued inside and the stator from a piece of metal tube or sheet metal. The capacitance would be changed by rotating the glass tube in the stator.

Try looking at this
http://www.jogis-roehrenbude.de/Bastelschule/Drehko-Eigenbau.htm

> As these capacitors will be work with RF, is it necessary to build
> with porcelain ?
> Is it ok to use PVC or similar material instead of porcelain ?

Beware of the problem that can be with PVC if it is colored the dye that
is used is often metal based. Using acryl is a good solution and is
more mechanical stabel than PVC.
To test if a material is OK for RF, try it in a microwaveoven together with
a glass of water, if it gets hot it is not good for RF.

Regards Max

FWIW: You may want to find a different list host. A lot of sites,
mine included, block all traffic from Yahoo Groups because Yahoo's
response to spam from same is lacking at best. As I recall, chunks of
Yahoo's IP space are also listed in the SPEWS database, which means any
ISP that uses SPEWS will not receive traffic from any listed Yahoo site.

Good luck.

Instead of tinkering with baby monitors, why not run an FRS radio as the exciter feeding into a frequency doubler? The 2.5kHz narrow-band deviation will become the 5kHz standard as used in Ham F3 voice transmissions. Also, if you double the frequencies of FRS channels 1 through 7, your outputs will range from 925.125MHz to 925.425MHz. This falls nicely into the 902-928 spectrum which has a secondary allocation for Ham use. Channels 8 through 14 however would land you out of band, and as such, would be a violation of our licensing. However, 7 cheaply accessible frequencies would be nice, as well as help keep a presence of some sort on the band. As far as receivers go, the simplest would be to use a secondary receiver, but if you're feeling in need of a homebrew fix, an outboard frequency divider would keep you busy for a few weekends.

For under-100 pFd variable capacitors of higher-power use, I
suggest an "plastic blade" type of variable. In such a form
the plates are fixed in position and a dielectric blade moving
in-out of the plates is the variable element.

The capacitance change ratio is much smaller with a
dielectric variable. Easy-to-work polystyrenes or even ABS
sheet material or G10 epoxy-glass substrate (without the
foil) has a dielectric constant of about 2.6. The actual
dielectric constant will be proportional to the blade material
thickness versus the total distance between plates (air has
a dielectric constant of 1). Dielectric blades do not have to
touch the plates. Spacing can be made adjustable and is
relatively easy to check using a micrometer. Capacitance
calculation formulas are accurate and found in many texts.

Use of plastic blades makes construction easier than
working with metal if there is no metalcrafting area in the
home workshop. Using a dielectric shaft with metal bearings
fore and aft, the dielectric blades can be epoxied to the shaft
at room temperature. Maximum to minimum capacitance
ratio will be somewhere between about 2:1 to 1.5:1 depending
on the blade dielectric constant and conducting plate
spacings. That form of construction avoids any noise from
conventional metal blade frame grounding contact on the
rotor shaft. It also has less stray inductance than a
conventional metal blade variable, important at VHF+.

I've had moderate success with that form about 30 years ago,
but seeking a specific variable-oscillator tuning that was

linear-frequency in rotation. Dielectric blades can be formed
by easier trimming than with metal blade variety.

I have a Drake TR-4 Xcvr. It has a Noise Blanker switch on the front, but there are no wires going from switch to anything...obviously the NB was removed.
There are 2 NB listed for the TR-4. A [34-PNB] & A
[9-NB]
The 34-PNB looks like it has a plug assy that would plug into a socket on the TR-4, but my unit has no such socket.
Does that mean my unit should have the 9-NB unit?
Does anyone know how to tell which NB should go with which model of TR-4?
Does anyone have one of these units for Sale, or a suitable equivalent?
Thank You for any assistance

<snip remainder of off-topic ad>

Right idea, wrong newsgroup. 'Homebrew,' in the context of amateur
radio (and if you had bothered to read the newsgroup header lines, you
would have seen that it says rec.RADIO.AMATEUR.homebrew), has NOTHING
WHATSOEVER to do with the brewing of any sort of drinks, nor does it have
anything to do with food or restaurants.

Within the context of ham radio, 'homebrew' refers to the design
and construction of one's own electronic equipment to serve a specific
purpose in the radio communications arena.

No one "owns" Usenet newsgroups, but I would like to ask, as a
long-time reader of them, that you please pay more attention to where you
post your advertising. Based on what I saw in the 'Newsgroups' header
line, you were right on target with 2 out of 3.

Thanks much.

Uh, wouldn't he then need a high gain 900 MHz amplifier to get the received signal up to where it could drive the divider? And what about the horrendous intermod that would generate? The last time I checked dividers were not very linear.

My vote would be for a an oscillator/mixer combination.

The 2-NB noise blanker is for the 2C receivers.

The 34PNB noise blanker is for the TR3 and TR4 transceivers.

The 4-NB noise blanker is for the R4C series receivers.

The 7-NB noise blanker is for the TR7 transceiver.

The 9-NB noise blanker is for the TR6 transceiver.

Sure, but I reiterate, a separate receiver would be the simplest. Secondly, the problem with using an LO to bring the rx frequency down is it would necessitate further processing to reduce the deviation of the rx'd signal. I do however, see your point on the intermod issue, so it's decided; we'll use outboard receivers... :)

hi guys, i have a heathkit HN-31 dummy load an i would like a manual for it and if anyone can let me know whats the maximum input power for the dummy load and how long can you keep the power in there on keydown can anyone help. plaese email me @ ve3elb@rac.ca thank you......

Yep, I've ordered a few times. I made a mistake in my order once and called back 5 hours later and they changed my order without a hitch. Friendly folks. It took 7-8 days to get my order but thats about what I get from other places as well.

950PF is about right, and I don't really need anything greater than a 0.08mm (0.031") gap.

(I know where to get one, but I'm hoping I can get a capacitor cheaper. :c))

Do you have one sitting around in your junkbox doin' nothin'.

MUST be double shafted, ie one at each end. 1/4" diameter.

I'm in Yorkshire.

Want quality, like a Jackson Bros item if poss.

Vince-

Check out the "Boat Anchor Manual Archives",
<ftp://bama.sbc.edu/downloads/heath/hn31/>, for scanned pages of the manual.

The manual has a graph showing how long you can use it for different power
levels up to 1000 watts maximum. It looks like 200 watts continuous. Maximum
depends on what kind of oil you use. Mineral oil is good for about a minute,
and transformer oil is good for about nine minutes at 1000 watts.

I recently picked up this very well made homemade device. It contains one vacuum tube which lights up when the cord is plugged in. It requires and oscillator input and either a coil or a capacitor input. It may tune for resonance to identify RF components.

Go to the newsgroup: alt.binaries.schematics.electronic
for a view.

Any idea of what it is? And if someone wants it, they are welcome to it for the price of shipping.

Al

Hello Ralph,

Seems your idea is the general consensus of the group. I only have an idea of what your suggestion is however. I can build circuits
with a schematic but my technical knowledge is limited so are there schematics available online you (or someone) could direct me to?

One poster (Max) gave a few web sites to check out. Are the schematics found there the type you describe?

Thanks for your help,
Vic

2945. small PLL transmitter ideas

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-20 04:16:46 UTC
From: Steve <Staticx9@optonline.net>
Message-ID: <Oapoa.49524$MB4.20406363@news4.srv.hcvlny.cv.net>
Source record: 35948

i want to build a small WFM transmitter to be used to hook up to a scanner or other audio device. it will transmit to my mp3 player which has a 76-109mhz receiver built in. reason being, i can record direct from radio into a *.wav file. 256MB can hold 18hrs of sound at 33khz.

i have built little kits and FM transmitters before, but most drift to much. i want to set it on one discrete frequency and thats it. most commercial units can only transmit 88-108 and are too large in size

-PLL locked or very very frequency stable
-76-88Mhz operation
-low power 10-20mW (20-40 feet at most)
-small size (to fit in radioshack project box cat#270-288)
box is 9/16x1-3/8x2-1/8 or maybe stack two on top
of each other
-able to run on single 3V cell (flat lithium)
-line level input
-can be mono, stereo is nto really needed

it seems like a lot, i just want some ideas, or if anyone has built something similiar if you have any tips please email me or post to let other know

thanks in advance

steve

2947. Homebrew double sideband

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-20 06:36:29 UTC
From: n2cqr@clix.pt
Message-ID: <97f305da.0304192236.5f9c82fc@posting.google.com>
Source record: 35950

With sunspot numbers declining I reluctantly decided to shift my portable one watt DSB HB transceiver from 17 meters to 20 meters. This rig is a very simple DC RX with a corresponding transmitter side. VXO is the only common stage. On TX, the VXO feeds an NE602 balanced modulator. I used an LM386 as the mic amp (that's what I had available). For the microphone I use an old SONY walkman mic.

On RX, I have a bandpass filter followed by an NE602 functioning as an RF amp. Balanced output to another NE602, this one the product detector. Then ANOTHER NE602 as an AF amp (again, balanced input) followed by an LM386. I get the NE602s to work as amps by putting five volts on pin 6. Nicest DC RX I've ever used. No common mode hum, even with AC supply.

Shifting from 17 to 20 was easy. Some 50 pf caps across the few tuned circuits brought them into the band. I got two new crystals from JAN (very nice folks) and rigged up a panel switch to go from one to the other. With the two rocks I can tune 14.185 --14.211.

I had some trouble with the carrier surpression, but I found that I could improve it by reducing the VXO energy going into the 602. Instead of the recommended 200 millivolts, I went to around 20 by using a "gimmick" cap (just two wires twisted together) between pin 6 and the VXO. By varying the amount of twist I could reduce the carrier to minimal levels. This gimmick was fun.

The rig is working very well. I'm getting 1-2 watts PEP out. In two days I've worked Spain, Italy, and the U.K. This morning I had a nice ragchew with K3LP in Maryland. It is a real hoot to tell people that they can switch to LSB and still copy just fine.

I don't think QRPers should be scared away by the big guns on 20 phone. And I think the simplicity of DSB makes it an ideal choice for homebrewers of intermediate skill level who want to break into the world of phone.

If you hear me, please give me a shout. USB or LSB!

Running 1 watt per sideband on 20m invites comparison to skateboarding
on the Ventura Freeway in North Hollywood during rush hour.

2953. (A little bit OT) Homebrew 9v battery gang charger?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-20 21:36:46 UTC
From: JLB <IHateSpam@nospam.net>
Message-ID: <4hEoa.55950$c42.55332@fe01.atl2.webusenet.com>
Source record: 35956

I have a need for a battery charger that will charge 4 or more 9 volt transistor type NiMH batteries.

All of the commercial units I have seen will charge multiple D, C, AA, or AAA batteries, but only one or two 9V, but I need to charge at least 4 at a time.

Is there such a thing, or will I have to homebrew it? Can NiMH batteries be trickle charged and then left on trickle indefinitely, like NiCads? More specifically, can they be charged with a trickle and then left in the charger until needed? This would greatly simplify the homebrewing if that is what I have to do.

I suspect you will have to homebrew it, but that's no disaster.

Yes

>More
>specifically, can they be charged with a trickle and then left in the
>charger until needed? This would greatly simplify the homebrewing if that
>is what I have to do.

Yes. If you can afford the time required to charge them at constant
trickle current. The difficulty with sensible charging of
cells/batteries is that:
(a) some charge termination system is required to account for variable
state of charge (SoC) when recharging is commenced; or
(b) you trickle charge them at a rate which recombination and heat
dissipation allow to continue indefinitely.

(a) can be fickle to implement, and is part of the reason there are a
literal horde of charge controller chips out there. As indicated
above, if you can bear a rate of 0.03C or so, then a constant current
gang charger is a simple exercise, using an LM317LZ per socket.

Have a look at http://www.powerstream.com for info on trickle rates.

There is also a current thread in sci.chem.electrochem.battery headed
"9 volt" MI-MH charging procedure using bench supply...
which may shed some more light.

2958. PCB Software - Thanks

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-21 09:30:46 UTC
From: Dick <dick@langwang.demon.co.uk>
Message-ID: <lz412xAGp7o+EwW+@langwang.demon.co.uk>
Source record: 35973

Thanks to everyone who sent me suggestions for PCB drafting
software. I now have more pieces of software than I know what to do with
.... but I'm going to have fun trying them all out !!!

==========
Could your NiMH 9V batteries in fact be 9.6 V ?.
I have a few ; they apparently have 8 pcs 1.2 v cell in series, their capacity is 160mAh
Charging instructions : 14-16 hrs @ 16 mA or 6hrs @ 32 mA.
Continuous trickle charging 4 mA seems OK
However before charging it is important to discharge to 1 Volt per cell ; in my case to 8 Volts.

In your case I would suggest you homebrew a combined discharger /trickle charger , to keep it simple.

Moderately academic in the context of CC charging.

Why?

There is little if any benefit to accrue from discharge-before-charge
on NiMH cells. OTOH, it may well contribute to a shorter life.

>In your case I would suggest you homebrew a combined discharger /trickle
>charger , to keep it simple.

That would actually complicate it.

Jan,
I would try to clock the chip directly, i.e. using the 50 MHz clock
and not use the PLL.

I'll see if I get some spare time to try a demo board from AD using
9850(?) and check the jitter. If so I will post the result for you to
compare.

Please let us know the outcome!

Or four of the single battery chargers??

That would cost two (or four) times as much. I could probably build one for less, and if I did so I would make it to charge six or eight at a time. Remember 4 was given as the minimum.

Junkbox Surplus Parts for Sale as of 04/20/2003
==========

NEW ITEMS

I have 200 excess pcs of 5.000 Mhz crystals. These are the miniture crystals like you see in the latest QRP Quarterly. Tiny round crystals with two wire leads, I think I've seen these in watches. If we ever get 60m these could be a lot of fun.
50 for $4.00 shipped to the USA.

I have 400 pcs of 102J (1000pf) Shinyei ceramic caps rated at 630 VDC. These are in bags of 200.
$5.50 for 200 including USA shipping.

I have surplus 50K 1 Turn linear taper pots, about 25 each. These are chassis mount pots with the nut. About the size of a nickle, and about 1/2 inch deep with a 1/4 inch shaft about 1/2 inch long.
5 for $5.00 including USA shipping.

2.5/5.5mm Coaxial Power Jacks for PCB insertion or Manhattan install
10 for $3.00

285pf Green Square Plastic Cap, PC Board Insertion 10%
100 for $4.00

220pf 5% 63V SMD Caps - Surface Mount size is 0806
50 for $1.00 PLUS you must send a SASE for return.

Odd Items
==========
9.8304 Mhz Crystals, 1/4 in tall - 20 for $5.00
27mH inductors with radial leads - 25 for $3.50

Caps - All new, old stock. No pulls.
==========
All caps now 50/$3 or 100/$5
==========
8pf NPO Ceramic - Loose
11pf NPO Ceramic - Loose
12pf NPO ceramics on tape

2971. Plexiglass/Paxoline supplier in UK

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-22 09:26:25 UTC
From: Richard <nearlynews_email@ntlworld.com>
Message-ID: <b831of$5tl23$1@ID-150848.news.dfncis.de>
Source record: 35974
Cross-posted to: rec.radio.amateur.homebrew,uk.radio.amateur

Hi. I'm in the UK and need some plexiglass or similar material. Needs to be pretty thick, about 1/4" or just under. It's for a roller coaster. Original material looks like bakelite or maybe thick paxolene, probably paxoline.

Anyone here buy this kind of stuff, and if so, can you recomend a supplier?

TIA. Rich.

2972. How to design a directive coupler for SWR-meter ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-22 10:35:44 UTC
From: Stephane Rey <stephane.rey@netcourrier.com>
Message-ID: <1103_1051007744@news.wanadoo.fr>
Source record: 35975

In order to design a SWR/Watt-meter, I would like to design
a directive coupler where the direct and indirect voltages will
be available. I wouldn't like to use PCB option because I
would measure about 50W.
I've ever seen some description, but I would like to find
information on how to compute and design this coupler.
The frequencies on which I would like to work are 2m and
70cm.

Thanks

2973. which coder for frequency adjusting ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-22 10:59:31 UTC
From: Stephane Rey <stephane.rey@netcourrier.com>
Message-ID: <1103_1051009171@news.wanadoo.fr>
Source record: 35976

Hello,

I'm designing a transceiver and I would add for the
frequency adjsutment a coder like the ones we can found
on the HF transceivers..

I've ever seen some coder but with holes and I would like
something as I've on my TS440 from Kenwood.

I've guessed to build an optical one with a disc and holes
and infrared sensor, but it's not a modern way and it's too
big.
I'm looking for a no expensive solution.

If you have some parts and suppliers to recommend to me it
will be the welcome.

Thanks
Stephane REY

Plexiglass is called Perspex in the UK. Paxolin is not recommended for anything that has to handle even moderate power or voltage - it absorbs moisture and goes lossy.

You should find plastics suppliers in Yellow pages - one I've used is Amari Plastics in Hedge End, near Southampton but I've no idea if they're still there. Another material to consider is glassfibre circuit board. Try a local pcb manufacturer, they are very likely to have pieces of thick material, often without any copper, in the offcuts bin.

For top notch material, ask the plastics people if they can source 'rexolite' (that's it's US trade name). Chemically I think it's cross linked polystyrene, but it's really good at rf.

Steve

2975. Eimac 8877 Tube & Socket For Sale

Stephane:

You might consider something a little different. I saw some information on the web about using a stepper motor as a digital encoder for a frequency synthesizer. Turning the shaft of the motor generated pulses to drive the electronics.

Stepper motors can be removed from many devices, including old computer disk drives, tape players, etc.

I'm sorry, I can't find the URL for it now, but perhaps someone else will have it.

An old timer at the Acton, Brentford and Chiswick radio club used to make roller coasters on his lathe out of plastic drain pipe. They were quite neat units.

Tufnol are probably still around, their material used to be popular for that sort of thing. You can also get perspex tube from plastics suppliers.

I don't know what this stuff I I have that is on this old roller coaster unit. It could be Tufnol. It's brown, shiney outside, and it looks to have a laminated construction. Probably is Tufnol rather than Paxoline.

I don't have to have Tufnol, but need something similar. Something that is not going to cost a fortune. Of the two, Tufnol might be better than Perspex, but I don't know. Maybe there is something better still, that is about the price of Perspex or Tufnol.

2979. help needed for experiment

Newsgroup: rec.radio.amateur.homebrew

From: Ben Veen <ben_veen@Hotmail.com>
Message-ID: <b83snu$248$1@news.tudelft.nl>
Source record: 35982

Hello,

I need help to do an experiment.

I have to design a system which can send 2 MByte of data over the world. I want to use a Fritzel GPA30 vertical antenna for that which can receive data at 14/21/28 MHz. I found some-one in the Netherlands that has such a system and now I am searching for somebody in the world to send a 2 Mbyte of data. The most ideal situation would be if it is a QuickTime movie. Also good is other data.

Do you know anybody who can send something at a given time and place to provide me with practical information about how the system works?

Greetings and thanx in advance.

Ben

Actually they are both Bakelite. Lots of trade names for bakelite
(Phonelic Resins).

http://www.sintetica.de/archive/body_archive.htm

I think bakelite is okay for RF purposes. Especially certain grades,
"Kite Brand" perhaps.

There ought to be and probably is a website that discusses relative
merits of materials for use in RF situations.

DigiKey and other have an amazing variety of shaft encoders, both optical and mechanical. They can be quite small, DigiKey has some nice little 9 mm encoders. They also can be quite inexpensive ... many are less than $3 U.S.

However, depending on your intentions, you probably want something that doesn't have detents, and you probably want lots of pulses per turn. This combination rachets the price right up.

..

Use the parts from an old mouse, for the optical disk you design
your own and print it on a sheet of overheadfilm.

You might get some ideas here

http://www.hut.fi/~jwagner/electr/rotary-enc/

It doesn't work _that_ well compared to a real tuning wheel,
although it really works quite well. At least the one I built has
slightly too few steps per turn to make turning it an all day
long enjoyment... ;-)) (maybe a different stepper motor would
work better)

cheers,

> Jan,
> I would try to clock the chip directly, i.e. using the 50 MHz
clock
> and not use the PLL.

Thanks, done that already, but it's much worse than with no PLL
for a given freq. As expected, really. Btw some 200MHz <25ps
peak-peak jitter <5ps rms jitter SAW oscillators should arrive
soon - I hope it works better with one of these.

About measuring: It's hard to say which equipment to trust - my
really ancient 10MHz analog scope shows a nice and clean sine
wave up to the freq the CRT is still readable, but OTOH, the much
newer and in all aspects more reliable 100MHz digital
scopemeter - with internal 20MHz lowpass filter toggled on -
shows "wobbles" and glitches along the sine curve. I'll go lend
another analog scope to triple check...

In theory, the DDS output filters I use should have
between -110dB to -100dB from 100 to 200MHz, IIRC. Maybe the
"standard" small 0805 size chip inductors aren't suited? What
type of filter components did you use?

Another alternative is that the filter is too steep, and the
"wobbles" are transfer function <=> inverse Fourier => time
domain sinc(x) function convolution with the input signal (sounds
like dead wrong maths, but _maybe_...)

OK...I was wondering if anyone else had problems. I ordered some stuff
from them that I needed. I also ordered some stuff that I did not need
but wanted anyway. Thay did not have what I needed it was out of
stock. They went ahead and sent the other items without contacting me
to let me know that they did not have the other items. I would have
cancelled the order had I known they were out of stock. It also took
them 3 weeks to get it to me. That is from Rhode Island to Georgia. I
was a little upset but got over it. I guess I will shy away from them
from now on or at least call them in person to make sure they have
what I want.

Tracy

Is this the one by Doug DeMaw and Wes Hayward, which came out in
1977, sort of a greyish cover? It was called "Solid State Design
for the Radio Amateur".

The ARRL did keep it in print up to at least a few years ago.
Unless saving money is the key, you might see if they still
have any copies.

(robrkx@nidhog.net) writes:
> Think there's a new version out.

I think they had a real reprinting at some point, complete with
a slightly different (maybe in color) cover. I remember excitedly
looking through it, thinking it had been updated, but it was
the same book.

What there is is "Experimental Methods in RF Design" by Wes
Hayward, Rick Campbell, and Bob Larkin which was just published
a month or two by the ARRL. They say it's the successor.

In a quarter century, I suspect they have pretty much brought
in new material, though likely the topics are the same (and greater).
I've yet to buy it.

But "Solid State Design for the Radio Amateur" is a book in itself,
and unless it becomes a collectors edition with collector's prices,
good to have no matter what other books you have. Like all
books that I use and rely on, I'm not happy that it would seem
to be out of print. I have plenty of books that are falling apart,
and I have to wait to stumble on replacements.

I would do a Google search on "inverting summing op-amp circuits". This would give you a simple way to go. There are plenty of single supply op amps available. You could then run the op-amp output into a simple IC audio amplifier circuit.

Watch the glass. Common grades don't insulate nearly as well as
Pyrex, due to impurities. I tried for years to make Leyden jars
from old peanut butter jars with no success. First trial with a
Pyrex food storage jar turned Leyden jar made the difference clear,
and in no uncertain terms.

FYI , I bought the 3rd Printing -1995 ,256 pages , in 1997 from one of the
Ham Radio Outlets for $ 15.00
It is one of the most stimulating 'homebrew' publications I have ever seen.

The above new book , including CD-ROM (I am going to order) costs $ 49.95

If the original book had the 509 pages of the new one and cost the same amount per page, it would sell for $42.25 in today's dollars. But you get a CD with the new book for the extra $7.70.

You said you needed 6 mm at least so I'm assuming you need to mend
an end plate? Perspex will do the job O.K. A little harder to work
than Tufnol, as it tends to crack if stressed, water is a good
cutting lubricant/cooler. I don't think Perspex would be a good
choice for the coil support, as it is easy to melt if you dissipate
any power in the inductor.

RS sell several grades of Tufnol, ranging from ï¿½20 to ï¿½70 per
580 x 290 mm sheet, 10 mm thick. Smaller quantities are unobtainium,
AFAIK.

You'll need to find somewhere that uses perspex to get small pieces
as off cuts. Let me know direct the dimensions of the piece you need
and I'll look in my shed. I can probably find ~30 mm x 10 mm x lots.
Wider pieces tend to be thinner. All mine came from judicious skip
harvesting.

3008. Binocular balun cores in push-pull amplifiers

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-23 17:07:20 UTC
From: wa5bdu@yahoo.com
Message-ID: <ca1a467b.0304230907.1932efff@posting.google.com>
Source record: 35911

I recently decided to build my first ever "linear" amplifier, a 10 watt design with two transistors in push-pull. It used binocular (two hole) balun cores for the input and output transformers. I thought those cores were kind of intriguing as to how they compare to toroid shapes. In discussions, I learned that they gave a higher coefficient of coupling in transformers. Also that you could make your own by gluing together parallel stacks of beads. So a common magnetic path for the two halves isn't needed? And, someone said, you can get half turns with one of these, but not with a toroid. Half turns?

If you sketch out an end view, with current entering one hole and coming out the other, you can see why magnetic coupling isn't needed or wanted between the two halves. If currents are equal, the fields from each side will cancel due to symmetry. And if they didn't cancel, the flux from one side would actually reduce the inductance when it links the other side, because it's "going the wrong way."

The half turn thing was kind of hard to believe, so I made some measurements on a BLN-43-202 core including whole and half turns and plotted L versus turns squared. The points fell on a straight line, so I guess that works.

Finally, getting to the question (almost). I was trying to figure the power output of my amplifier from the transformed load resistance with the familiar R = (Vcc^2)/2Po rule. But it's a little complicated by the fact that the transformer is center tapped on the input side. The transformer has one turn on the primary and two on the secondary. The primary is U-shaped. Its free ends are connected to the collectors of the two transistors. At the other end of the core, where the conductor exits one hole and reenters the other, is the center tap point that connects to Vcc. Tapped at one-half turn, I guess you'd say.

Now look at the action of the transformer. I guess it's accurate to say that the transistors take turns conducting on alternating half cycles. So in a given half cycle, one half of the transformer is a transformer, with 2:1 ratio. The other half doesn't have any primary current driven through it. But the secondary turns do go through it, so it's really an inductive load in series with the transformer and load. Is that right? Doesn't seem like it could be, given that this circuit is popular and it works. What's really going on? Is some phenomenon I don't see balancing the currents? Should I not worry about it and just get a life?

3009. Re: How to design a directive coupler for SWR-meter ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-23 17:54:00 UTC
From: k7itm@aol.com
Message-ID: <3200347.0304230954.3e8c10c3@posting.google.com>
Source record: 35912

I'm a little surprised that after a day I haven't seen any other replies to this. I'll take a stab at it.

I suppose most people these days would use a fields program to iteratively get the design they want. Certainly there are some folk around that would understand the fields well enough that they would just work it out on paper. But I think you can do fine by just building a section of line with air dielectric and of the impedance you wish, and putting a straight wire parallel to the axis of the line, between the inner and outer conductor. Adjust the spacing to get the coupling you wish. Put the wire nearer the outer conductor for lower coupling. If you load each end of the coupled wire with the right resistance, the response should be proportional to "forward voltage" at one end and "reverse voltage" at the other, as the drop across each resistor is the sum of currents from a capacitively-coupled component (same polarity across each resistor) and an inductively-coupled component (out of phase in the two resistors, as it is current around a loop).

It can be very convenient if the load resistors are each 50 ohms. By adjusting the geometry, you should be able to make 50 ohm loads work. "Details left as an exercise for the reader."

I know that there have been construction articles for such couplers. I believe in the old ARRL VHF manuals there was one or more such article. More modern books probably have them as well. There may even be some decent ones posted on the web.

By the way, if you build it carefully, you should be able to get phase as well as amplitude information from it. Obviously, I did not mention how to detect the RF at each port, but certainly it is possible to detect both the amplitudes and the relative phase, which can be much more useful than just the SWR which considers amplitude only.

Cheers,
Tom

I was at Sear's last week for the first time in a few years, and
took some time to look over the tools. There were a number of Dremel
accessories that I hadn't seen before. One was a gizmo that held
the Dremel tool for cutting things. It seemed like one was supposed
to use a carving bit, and the gizmo held the tool vertically against
the surface to be cut. It looked like it might be useful for cutting
circuit board, but it was about $20 Canadian and I wasn't feeling like
spending the money to check, at least not at the moment.

Those cutting discs are great, but they aren't that useful when
cutting away from the edge of the board. The rest of the tool hits
the surface before the cutting wheel has a chance to reach the
board. I suppose one could cut at an angle, but this would only
increase the breakage of the discs.

Also The length of the line should (I think) be short in relation to the line wavelength. Also the length will affect the coupling.

Tom do you want to add more details regarding this.

Half turns?
==========

Easy!

Two parallel ferrite cylinders. One 1/2 turn goes up one cylinder and the other 1/2 turn back down the other. The ends of the single (or N) turns are connected to the collectors of the push-pull output transistors. The DC supply is connected to the half-turn(s) at the opposite ends of the cylinders from the transistor-pair.

For a simple circuit analysis and impedance matching involving a pair of parallel ferrite cylinders download in a few seconds small program LINEAR1 from website below. No unzipping inconvenience, run immediately. Just remember impedance matching must go in STEPS of impedance or rather voltage ratios.

Download program LINEAR1 for design of simple push-pull transistor, class AB, HF linear power amplifier. You will need to think clearly about what you are doing. It turns out you are not involved with impedance but voltage ratios. Voltages depend on DC power supply volts and load resistance and not on the internal impedances of the transistors. Knowledge of transistor internal impedance is unnecesary. KISS.

> ** 468/f seems to work ok.
==========

You've been reading old-wives' tales again.

Of course, with radio, any bloody thing will WORK.

At least it might work good enough for YOU.

But there have been 300 world-wide downloads of this program in the last 24 hours which indicates 468/f does not work very well when it comes to very low Inverted-V's.

Within minutes of the program being available on the newsgroups there was an e-mail from a station wishing the program had been available a week earlier.

He had just spent condiderable time and labour pruning in little bits the wire down to size after initially errecting a wire several feet longer than necessary just to be on the safe side.

He ended-up with the same antenna length as predicted by the program. Or rather the same resonant frequency as predicted by the program for his particular antenna dimensions.

You have probably never had an Inverted-V, the poor man's high horizontal dipole. Nevertheless your comment is not altogether out of place. Thanks.

Group gurus:

What effect does the dimension of the ferrite core have on the ability of a loopstick antenna to acquire a signal?

Put another way, suppose I have one ferrite core, say 1/2 inch in diameter and 4 inches long, and another the same diameter, but 8 inches in length? Any differences in the electrical characteristics of otherwise identical coils wound on each? Any differences in Q?

How about a 1/2 inch core versus a 1 inch core? (Assuming #turns are corrected so each coil has the same inductance) Any DX advantages to a core of absurd dimensions (3 inches diameter, 3 feet in length?)

TIA

Bill,
I can build a simple receiver with a loopstick, cap, and diode. There is no converter. That simple receiver will pick up a.m. stations without the benefit of an external antenna of any kind. While the loopstick is part of the L/C tuning circuit, in this application it is also a receiving antenna in its own right.

I have a WWV receiver that uses a loopstick antenna for signal acquisition, and nothing else. I think the circuit that follows amounts to a TRF receiver with a PIC chip for extracting the time data. Different frequency, but the idea is the same.

So let me state the question again....given windings that yield an inductance appropriate for the specific application, is there any benefit to be derived from making the ferrite core either longer, larger in diameter, or both?

3024. Re: Unusual Question About Loopsticks

Source record: 35927

There was an application book by National Semiconductor published in 1980 titled "Audio/Radio Handbook" which contains bits of information I haven't seen anywhere else. The following is from the "AM Radio" section:

The effective height of the [ferrite loopstick] antenna is a complex function of core and coil geometry, but can be approximated by:

Heff = (2 * pi * mur * N1 * A) / lambda

where

N1 = total number of turns
mur = relative permeability of antenna rod
(primarily function of length)
A = cross sectional area of rod
lambda = wavelength of received signal

It gives as a reference "Laurent, H.J. and Carvalho, C.A.B., 'Ferrite Antennas for AM Broadcast Receivers,' Application Note available from Bendix Radio Division of The Bendix Corporation, Baltimore, Maryland."

I recall that the Fair-Rite web site has graphs of effective permeability vs rod permeability and length. The Amidon flyer had these graphs also.

Theoretically, increasing the core diameter increases the number of lines of flux captured from the external field (just like increasing the diameter of a coil or antenna wire), and therefore increases its sensitivity, all else being the same. But any ferromagnetic material creates noise because of the Barkhausen effect, which has already been determined to be the primary factor that limits the sensitivity of a ferrite rod antenna. IOW, a larger core will increase your signal, but it will also proportionally increase the amount of noise. So even if you do find an absurdly large core, your S/N ratio isn't going to improve beyond the limit that has already been established with commercial radios.

Increasing the length of the core will increase it's directivity, as you can see if you ever get the chance to play with one of those old marine DF receivers that use really long ferrite rods in the direction dials (Ray Jefferson made quite a few). Directivity has some advantages for DXing, but none that can't be had with a traditional loop.

Perhaps this might be useful as a reference point - I recently ran rms jitter measurements on some AD9835's with a 50MHz crystal clock using an HP5370A with time interval averaging and a Motorola 100EP16 ecl differential line receiver using hysteresis as a zero-cross detector.

The crystal had about 25ps rms jitter, and you could see the variation in the AD9835 output as the output frequency ratio changed from exact integer to non-integer. Above 1MHz, the rms jitter changed from about 60ps to roughly 300 ps.

Below 700KHz, the rms input noise of the EP16 starts to dominate, but I never saw the large amounts you posted.

Here is a log plot of the data:

http://www3.sympatico.ca/add.automation/misc/logplot.gif

Below is the raw data:

MHz RMS Jitter (ps)

5.0 55
4.9 253
4.8 171
4.7 157
4.6 156
4.5 184
4.4 128
4.3 112
4.2 111
4.1 195
4.0 129
3.9 186
3.8 198
3.7 138
3.6 134
3.5 142
3.4 179
3.3 209
3.2 154
3.1 201
3.0 148
2.9 195
2.8 227
2.7 175
2.6 242
2.5 58
2.4 227
2.3 199
2.2 181
2.1 261
2.0 74
1.9 252
1.8 357
1.7 188
1.6 334
1.5 249
1.4 344
1.3 322
1.25 139
1.2 355
1.1 321
1.0 148
0.9 344
0.8 357
0.7 378
0.6 531
0.5 441
0.4 547

0.3 1210
0.2 1320
0.1 2080
0.05 2870

From these results, I would hazard a guess there might be noise entering the system to give the results you are seeing, or there is something funny about the measurement. This is not much help, I know, but when you are dealing with wideband signals, the noise can come from anywhere.

Also, there might be noise on the power supply itself, especially if you are using a wall-wart. I posted an article on different ways to reduce it that might be helpful:

http://www3.sympatico.ca/add.automation/spice/ripple.htm

You might look at bypassing and grounding, parasitic oscllations, keeping lead lengths to a minimum, and all the other techniques needed for rf work at high frequency.

As far as getting 100dB attenuation from the DDS filter, that is difficult to do without extreme care in layout and shielding, especially above 100MHz.

A designer of a commercial product is limited by various constraints, such as the size limited by the receiver box or the manufacturing cost of the device. The designer has the find the best compromise while these restrictions apply.

However, in amateur experimentation, these constraints do not necessary apply and the other parameters can be optimised in different ways.

Some experimenters glued multiple loopsticks end to end to create a long loopstick (1 m), others made a bunch of multiple loopsticks and would the coil around the bunch. I don't know which is the most effective way.

Quite true. According to my dipmeter, a 75m-band dipole, 2m above
ground, resonates about 8% lower than one at normal heights. I don't need
a computer to figure 8%. However, making a low dipole resonant does not
result in a low SWR since the radiation R at resonance is much less than
50-ohms.

the safe way is to fold the ends of the dipole back on themselves so
that the length can be adjusted longer or shorter as needed with out
soldering..

&#65533; Good point. Increasing the length of the core also increases signal level. so less amplification is needed. I build 160m, 75m/40m direction finders with 3, 7'5" by 0.5" u=125 ferrite rods taped end to end, wound with hookup wire, and laid in 24" of Aluminum right-angle stock. I found the null to be surprisingly sharp and the resulting signal level could be amplified adequately with a simple untuned emitter-follower. Using this apparatus, I measured 75m and 40m signal arrival angles during day and night. The arrival angles were higher than is popularly believed. Also, near sunrise, arrival angles fluctuate widely.

What do you mean by "effective"?
For better directivity (sharp nulls) a long stick is certainly doing better
than a short one.
Built one myself recently for this nice 80m ARDF RX:

A common test for plastics is to put a piece in a microwave with a cup
of water (you never want to run a microwave empty).

If the water gets hot but your test piece stays the same temp, then
that plastic does not absorb much RF at microwave frequencies. We
generalize this to believe that it absorbs little RF at frequencies of
interest.

Real RF testing is not a trivial process, this something easily
accessible.

Hi
Does anybody remember the White Rose rx, designed by John Hey ?
While sifting through some packing cases in the 'workshop' the other day I came across a set of part-completed circuit boards for one of these - and thought I might give it a try.

I have a copy of the original details (?Radcom?) - in which it stated that a matching Transmitter would be available soon. Does anybody know if this ever happened - and , if so, maybe has a set of details that they'd be willing to share ??

Thanks in advance

More about two-holers:

Does the formula L = A*n^2 work for inductors, even with half turns?

Since the two halves don't communicate with each other, you can just take the sum of the two inductances so,

L = A*[(N1)^2 + (N2)^2], where N1 and N2 are the number of turns through each hole.

N1 & N2 are equal for "integral turn" inductors and differ by 1 for "half turn" inductors. For a "half turn" version, the inductance will be

L = A*((N+1)^2 + N^2), which reduces to

L = 2A*(N^2 + N + 1/2)

Now, assume the same basic formula works when treating the entire inductor as a unit and allowing half turns. Now the efffective A is 2A. So consider the same inductor as above with the same number of turns, which now is N + 1/2 turns.

L = 2A*(N+1/2)^2 reducing to

L = 2A*(N^2 + N + 1/4)

The two resulting formulas are not equivalent. Close, but no cigar. Treating the whole thing as an inductor with half turns results in a calculation that is low by A/2 inductance units, regardless of the total number of turns.

Back to transformers. The transformer with a one turn primary and two turn secondary can be considered to be two such transformers, with their primaries and secondaries in series. That's pretty much academic regarding analysis except, getting back to my original question, what is the effect of this arrangement in a push-pull circuit where only one primary conductor is being driven at a time?

Dang, Bill called my bluff. Before I try to explain any deeper, I
want to be very sure I have a clear understanding of the details
myself.

Here's a web site that has a fairly detailed analysis of coupled
microstrip: http://www.ee.bilkent.edu.tr/~microwave/programs/magnetic/dcoupler/theory.htm

If the math scares you, at least have a look down at the summary at
the end of section 1. It discusses length, among other things. There
is certainly not a need that the coupled section be very short...that
is, you don't have to think of it as a simple sampling of current
(magnetic field) and voltage (electric field) at a point, but it works
as a distributed system.

I had a look in the books I have at home last night, and didn't find
what I wanted there. But I did note that the old RSGB VHF/UHF manual
has a pretty good section on directional couplers, with both
construction articles and some general theory. Somewhere I have a
file folder of articles on various couplers; maybe it will yield
something.

I wonder if Kevin Schmidt still reads this group. I've found his
explanations of transmission line (and other) fields to be uniformly
excellent, and I've learned a lot from them.

More later if I learn enough to add something useful.

Cheers,
Tom

I messed around with DF rods a few years ago but I never found that length added much signal. I did notice that, like you said, the nulls are very sharp, and even seemed to be sharper than loops (subjective opinion).

The best preamp I found was a pair of triodes in cascode -- worked even better than an FET (go figure).

As for the arrival angles, are you sure you weren't phasing ground and skip?

Very irritating pages, with lines that run off the edge of the paper
due to the construction of the HTML, but very enlightening.

<< I have to design a system which can send 2 MByte of data over the world. I want to use a Fritzel GPA30 vertical antenna for that which can receive data at 14/21/28 MHz. I found some-one in the Netherlands that has such a system and now I am searching for somebody in the world to send a 2 Mbyte of data. >>

Ben-

There are popular Amateur Radio systems that are capable of sending data over long distances. These are primarily teletype-like systems such as Amtor or Packet Radio.

One thing that characterizes them, is their extremely low data rate when used on frequencies that have around-the-world range. I understand that below 29 MHz in the U.S., the data rate is limited by law to 300 Baud, and to 1200 Baud between 29 and 29.7 MHz. The throughput rate is usually less because transmissions must sometimes be repeated many times to overcome noise and interference from other station's transmissions. Therefore, sending a large amount of data requires a large amount of time. In other words, you won't be able to view a QuickTime movie at full speed until all of the file has been received.

And it isn't simply a matter of law. You are not likely to find equipment capable of sending data on those frequencies at a much higher data rate.

You don't say how much of the system your design must include. You might simply specify use of Amateur Radio transceivers coupled with Packet modems and terminal software, at each end of the link. Such a system might be able to send the data over the 14, 21 or 28 Mhz bands, but only when conditions are right for the required path. On 14 MHz you might be able to send the data at some time during a 24 hour period. On 28 MHz, you might have to wait several days for conditions to be good enough to support sending the data, and just hope they stay good long enough to send it all.

An alternative might be to send data over a network of packet radio stations. The effective data rate would be even lower, but transmission over the network might be between numerous stations that are close enough together that they do not require any over-the-horizon paths. Some of the paths may even be via internet!

I remember the Rx article although I don't recall RadCom ever publishing a
companion Tx. Perhaps John designed one, though, and didn't write it up. I
think that 'White Rose' referred to a club - in Lancashire? They might have
a web site, or you could get their details from the RSGB and contact them.

If you already have the preamp, just add a loop. If you want a tuned loop, try
this:

http://www.aimcomm.com/sparky/rad03.txt

If you want to get really radical, try some research on negative impedance
converters.

==========
FYI ,some time ago I made a DF rx for 160 m with a ferrite stick antenna from an old valve type BC rx.

The ferrite stick antenna was fitted inside a circular aluminium pipe cut such that there is a 2mm slit over its entire length.
The ferrite rod was subsequently fitted concentrically with polystyrene discs at each pipe end.

If necessary the antenna can be waterproofed by covering the slit with tape.

> tune circuit).

There is so many of them out there, so it might be a
good idea if you did supply some more info.

What freq. range is of intrest ?

The size of it ?

Outdoor or indoor ?

Remotely tuned or not ?

Do you prefer special mechanical type of design ?

Regards Max

HI Leon

Thanks for the reply.

I don't remember Radcom publishing the TX either <g> - but I did see a reference on the web to the transmitter, and it was certainly mentioned in the original article.

There is a website for the White Rose Radio Club - I emailed them some days ago and I'm still waiting for a reply <g>

I've also found John's snail-mail address on the web - so if all else fails I could write him a letter.....

Thanks again

news:<3200347.0304240945.60db65ba@posting.google.com>...
...
> More later if I learn enough to add something useful.

(Yeah, Mike's sure right about the terribly annoying formatting on
that web page.)

I put together a model of two coupled lines. The model is
conceptually simple, just L-C sections in Spice. Each line in each
section is 1e-13 farads shunt and 2.5e-10 henries series, or about 1.5
millimeters of line length, for air-dielectric line. The coupling was
1.01e-15 farads and k=0.01, which I expected would give a -40dB
coupling. I used 104 segments like this, in series, to represent the
coupler. That's about .1559 meters of line, which is a quarter wave
at 480.7MHz. The model shows -40.00 dB of coupling at 480MHz, and the
same coupling at 1.44GHz, which corresponds to 3/4 wavelength.
Presumably that continues at odd quarter waves. That means...if you
are willing to make a coupled line that long...that if you use a 1/4
wave coupled section at 146MHz, you will get the same coupling at
438MHz. The "directionality" from the model was 40dB at the 1/4 wave
frequency and 33dB at 3/4 wave. That is, the response to the port
that is supposed to be quiet was 40 and 33dB lower than the response
to the coupled port. And that's probably an artifact of the segmented
model. (An actual implementation will have other defects limiting the
directionality, I'm sure.)

At lower frequencies, the coupling drops off, following a 20dB/decade
asymptote. Coupling at 4.8MHz in the model is -76.1dB. And at 1/2
wave (960MHz), there is a deep null in the coupling. The coupling at
480MHz +/- stays within 0.01dB of -40.01dB from about 458MHz to 499MHz
(slightly non-symmetrical about the peak response). The 3/4-wave
response is similarly flat from 1.414GHz to 1.456GHz. That's
certainly dead-flat for any amateur application, and if you scale the
freqs listed above, you can cover 141.5-154.2 and 437-450 with a
single coupler with equal, flat coupling on the two bands. Only
problem is that the coupler has to be 50 cm long, if it's
air-dielectric. Perhaps a more practical 33cm (13 inches) if we can
do it with polyethylene dielectric...

Anybody think this would be worthy of a construction article if I can
figure out how to make it practical?

(Don't read too much into the absolute numbers from the model. With
so many segments, and especially at low freqs where the reactances are
quite small, we should expect some roundoff error. I'd guess the

20dB/decade is accurate, and I'd guess that the "real" asymptote may well pass through a point 3dB above the -40dB coupling peak, which would imply -77dB at 4.8MHz.)

Math/fields whizzes can undoubtedly confirm or refute all this Spice modelling easily with an analytic model. :-)

Cheers,
Tom

R There was a supporting wood post at each end of the wire. I stood at
the middle of the dipole with a dipmeter and measured the resonant
frequency. Presumably, the resonance lowering effect was brought about by
the additional capacitive loading at the ends caused by being closer to
ground.

cheers, Wes.

|ï¿½ There was a supporting wood post at each end of the wire. I stood at
|the middle of the dipole with a dipmeter and measured the resonant
|frequency. Presumably, the resonance lowering effect was brought about by
|the additional capacitive loading at the ends caused by being closer to
|ground.

But you said that there was an 8% change going from "normal" height
(which is???) down to 2 meters high. So if "normal" is 15 to 20
meters, I guess you stood on a 15 - 20 meter high post and grid dipped
there too. Right?

I modeled a 75 meter dipole at heights of 20 and 2 meters and found
about 1% change.

Also, don't you know---ooops of course you don't---that the impedance
of a 2 meter high, 75 meter dipole over average ground, has an
impedance *greater* than 50 ohm (~60), not lower. So your other
unsubstantiated old wives' claim is untrue also.

A few minutes with even the free version of EZNEC would serve you
well.

3069. Re: AD9854 DDS "wobble" question

>type of filter components did you use?

You have to choose these inductors carefully. I have tested half a dozen
different brands and discarded most of them. Coilcraft ones are pretty
good, but none of the brand Digi-Key carries are useful with this device.
If you use an eliptical filter, your Q at the passband edge has be high.
Use this cheesy little program to calculate Elip filters.
(http://novatech-instr.com/Software/TOOLS/ELIP.C) There are better programs
around, but this one gives the right answers.

>Another alternative is that the filter is too steep, and the
>"wobbles" are transfer function <=> inverse Fourier => time
>domain sinc(x) function convolution with the input signal (sounds
>like dead wrong maths, but _maybe_...)

Well, you can get ringing due to the fact that the sine wave is a
step-wise approximation. This little steps "whack" your filter to
generate "wobble".

>> I'll see if I get some spare time to try a demo board from AD
>using
>> 9850(?) and check the jitter. If so I will post the result for
>you to
>> compare.

Remember that no matter how good your filter is, there are code
dependent spurs at 60-70dBc down on this device and can also show up
in your output. Your bypassing and board layout has to be really
good. Also, the PLL pin is EXTREMELY sensitive to pick up. A PC monitor,
5-10 feet away will modulate your output. A phase noise plot makes this
easy to find. Put your UUT in a metal box for testing.

>Yeah, would be interesting if you could post some numbers! :-)

You should see about 25ps RMS, or about 200ps P-P.

My first thought is that if the aluminum channel is solid (already assuming it's
tubular, but 'solid' meaning not perforated or cut with slits), wouldn't eddy

currents in the shield detune the coil and/or attenuate the signal? Or was this stick for VLF?

Either way, my idea was more along the lines of wrapping it up in some ribbon cable tied together at one end.

Interesting. I gotta play with that myself.

DVR 2-2 users:

I have a DVR 2-2, and I lost the power cable for it. I need to know what is the type of connector on the back of the DVR 2-2, and where can I purchase a plug that mates with it that I can use to build a power cable for it!

From: wb8rcr <wb8rcr_nospam@qsl.net>
Message-ID: <valdsrsl1bgi36@corp.supernews.com>
Source record: 35841

A few weeks ago, I announced the release of an updated version of Dial for Windows which allows a control to be rotated.

That same capability has now been added to the platform independent/Linux versions of Dial and Panel. Both are now available at http://hfradio.org/wb8rcr. On the left, click on "Panel (not QSLMaker)" to get to the Dial/Panel download page.

These are all free, open source, no strings.

Enjoy.

3079. FRS Radio

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-27 03:03:45 UTC
From: ValleyArts1@webtv.net
Message-ID: <26538-3EAB4891-646@storefull-2173.public.lawson.webtv.net>
Source record: 35846

Does anyone know if any of the frs type radios are employing phase modulation instead of the more common fm?

3080. FRS Radio headset wiring diagrams or schematics: 5200 series and 6000 series Motorola

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-04-27 03:16:23 UTC
From: Ron <Ron@onwisconsin.com>
Message-ID: <4somavsd99mu1ngokep9phiuhohs706nbn@4ax.com>
Source record: 35847
Cross-posted to: alt.radio.family,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.misc,rec.radio.swap

Greetings!
I have been trying for several days to find anything in the way of schematics for the 5200 and 6000 series FRS hand held transceivers. My need is to design a simple intercom/ interface system for use with these radios while riding my motorcycle with my wife as a passenger. Searches have rendered many sites that sell millions of these units but no tech talk.
The units that are on the market from HJC Chatterbox as well as Nadi don't do everything I would like them to do and are pricey too.
At the very least A simple headset/mic wiring diagram would be useful and welcomed.
Discriminator line tap point and squelch amp line location is needed too, hence the need for complete schematic.
I have e-mailed Motorola but have not received any reply as yet.
Thankyou for your time and consideration.
Ron

Duncan, you'll probably have an easier time finding a 3.8-4.0 MHz rock and
dividing it by two.

3082. Transverter HF to 2M

Or for that matter, any crystal that divides down to 160m. Once
the divider is in place, it doesn't really matter if the crystal is
twice the signal frequency, or higher.

Indeed, if someone is looking for multiple frequencies, use
an oscillator that won't need fiddling with changes of frequency,
and then uses something like the 4024 7stage ripple counter. I suppose
it would be 74HC4024. Then if one crystal is twice the frequency,
use only the first output, while another crystal might be 4 or
8 times the frequency, and the suitable output would be selected.

==========
An excellent design can be found in VHF / UHF DX Book , edited by G3SEK
The first edition I have is labelled ISBN 0 9520468 0 6
It should be available in the USA ,possibly through ARRL.
It is meant for transverting 28 - 30 MHz to 144-146 MHz using a 116 MHz
crystal
If the transverter is also to be used in ITU-Zone 2 with 144 -148 MHz
amateur allocation an additional 118 MHz crystal will be required , unless
the HF transceiver is converted to wide band use (usually done by
removing/clipping a jumper)

I believe Ten-Tec are selling a kit for a HF to 2m transverter

Ron,

It's highly unlikely.

In order to get the rquired FM deviation from PM, you have to have to generate the PM at a low frequency and go through a number of frequency multiplier stages. With modern implemenataions (FRS is a pretty recent thing), everyting is done 'on frequency' with PLL control. That's the only viable way to make it so simple, power efficient, and cheap.

'Linear Transverters for 144 and 220 MHz' by Paul Drexler
WB3JYO from the ARRL Handbook 1993.

Google for JAVORNIK-144/14 transverter.

I have recently built two 10M/2M transverters. I will
put the details on my web-page, eventually...........

As a sidebar, ANY modification to the radio will void the type
acceptance from the FCC, and it would no longer be legal to use.

But as Joe says, they are designed to be inexpensive and not to be
worked on.

Happy trails,

"An alternative might be to send data over a network of packet radio
stations.
The effective data rate would be even lower, but transmission over the
network
might be between numerous stations that are close enough together that they
do
not require any over-the-horizon paths. Some of the paths may even be via
internet!"
......

Does that mean one should have to search for friends in order to use their
packet radio station?

Source record: 35859

If I make an amplified aperiodic (untuned) loop antenna, what is the best approach for the
antenna coil? Ferrite bar or a larger loop?

How do you determine the best inductance for a given frequency span--say LF through 3 MHz, or would that have to be done with taps on the loop?

Peter

Jan
I cant access your scope pictures.
However as you know I have built a similar board (didnt I send you one?) and the output of mine was superclean, both on a spectrum analyser and a scope. It was also pretty clean to listen to on a receiever. I didnt measure jitter as such but in theory the random phase noise of the DDS should be pretty good, nearly as good as its clock. The CMOS process should yield figures from the DDS itself of a noise floor in the region of -140 dBc/Hz. The PLL clock multiplier will degrade the clock source somewhat by 20 log N dB where N is is the multiplication ratio, plus a bit for other factors. The problem of course, is discrete spurs which are about -50 dBc worst case but they should be better than this at 1 MHz with a 200 MHz clock.
Looking at your construction, I suspect there is an error there somewhere as it damn near impossible to construct those things without a masked PCB. Have you got a separate ground plane and supply for analog and digital sections? Are there any earth loops? Are all the relevant pins grounded? Is the comparator switched off as you dont seem to be using it?

Hi
being somewhat confursed about the information from some sources I
wonder if it is a site where more practical information is presented
for building an antenna for transmission on ham bands

I could start with 40m, but 160M is also useful, and not at least
would be needed an antenna for 136kHz if possible

I'd think the coax phasing lines are the least critical to set up. A simple trimmer cap can be used to precisely set the desired 90 degree phase shift.

The audio phasing is very critical, and it is difficult to maintain the 90 degree phase shift AND the levels over the range of 300 to 3,000 kHz. There are better means to do the audio phase shifts than the B+W which was only rated to be within 1.5 percent of 90 degrees.

No that won't make any difference. Have you put your output up on an
spectrum analyser?

Again, make sure there's no pickup on the PLL pins (shielding).

I will see what I get at 1.47MHz with a 200MHz clock. I should be able to
put a photo up.

Message-ID: <vaol1g7jnivu33@corp.supernews.com>
Source record: 35808

I don't know specifically about FRS, but it's standard for communications and FM broadcast gear to use pre-emphasis. This causes a frequency deviation that's directly proportional to modulating frequency above the pre-emphasis break point -- that is, over most of the audio range. Over this range, the modulation is identical to PM with no pre-emphasis. So pre-emphasized FM, which is the standard, ends up producing modulation that's the same as non pre-emphasized PM over most of the audio range. Some or most older commercial communications gear just used PM for modulation, using a de-emphasis circuit to flatten it out below the pre-emphasis breakpoint. The result was identical to pre-emphasized FM.

<< Does that mean one should have to search for friends in order to use their packet radio station? >>

Ben-

It has been many years since I was active in Packet Radio. Back in the late 80s and early 90s it was possible to send messages equivalent to today's internet E-Mail, using "bulletin boards" as message servers. Those bulletin board stations passed messages along the existing network of packet radio stations. The messages were routed to the specific bulletin board station where the recipient would retrieve the message.

If you knew where packet stations were located, you could connect to a more distant station by specifying the route to be used. Your message packets would be relayed through each successive station until it arrived at the distant station. Once you were connected, you could send a message to the distant station. If I recall correctly, some systems were being developed that could route the connections automatically using the destination ZIP code.

There were some stations using TCP/IP protocol over Packet Radio. Using TCP/IP with ftp (file transfer protocol), those stations could upload and download files from their station to the distant station. I think this method would be your best bet. I expect software is still available, but I don't have any personal experience doing this.

After all this time, I expect there have been developments in Packet Radio I haven't heard about. I'm not sure the networks have extended throughout the world, but you still might be able to transmit your file with a single hop if you choose the right frequency and the right time.

Cross-posted to: rec.radio.amateur.homebrew,uk.radio.amateur

Hi. Has anyone got a turns counter for sale or a pair of turncounters? Maybe you have something ex equipment. Needed for 37 turns rollercoaster. Probably is not digital, (too expensive) but readout dial is probably just a circular disc or ring. Shaft on roller coaster is 1/4 inch. I'm in UK.

A very simple lpf can do this too, one serial coil followed by one parallel cap.
It's used in vhf helical duplexers quite often instead of space hogging coiled
up 1/4 wave coax lines.

Thanks everyone for all your suggestions.
I am sure we have plenty to go on now.
I do think though that the PLL synth idea is a little like taking
a sledgehammer to crack a nut!

> Serge /f5jtm

There has been mention in the thread of using coax sections for phasing. You could also use a quadrature (90 degree) 3dB hybrid. You can build one from line sections, or from lumped components. It's fairly simple, though more complex than just a 1/8 and a 3/8 wave line. I believe it will give you a more stable phase difference than the simple lengths of line. It is also a directional coupler, though you probably don't care about that for this application. You can probably find details with a web search. You'd connect the quadrature outputs to mixer LO inputs through lines or whatever that were matched, so the phase difference is preserved.

Cheers,
Tom

Actually, by leaving the CE enabled all the time, you gain about half the access time with the older chips. Many of the older 2716 eproms are 450ns or 350ns. Setting CE on all the time and using OE to toggle output, will give you about 200 to 150ns access time or better.
I've used a similar design for an IC-271A no-fail memory, using a 2716 and 6116, with CE enabled all the time with no problems. It all depends on how fast you want to push the Z80 in your design.....

I assumed you'd want to do it directly at 144MHz; otherwise, why talk
about 2m? If you do the generation and detection at an IF frequency,
then the RF part is just mixing and linear amplification.

But no matter, a quadrature hybrid can be done at low frequencies with
lumped elements (inductors and capacitors). Similarly, the phase
shift of transmission lines at a single frequency can be done with
lumped components as well. Of course, you can also do it by starting
at four times the (IF) carrier frequency and dividing down; you can
get pretty good quadrature that way.

Cheers,
Tom

Hi Serge,

I'm sorry, I hope it did not sound like I was making fun of your English! I have great admiration for people who can actually communicate in languages other than their native one.

But I do think that phasing directly at 2 meters might be interesting for you, if you want to keep the whole thing very simple. In fact, if the r2/t2 design is what I think it is, can you not just do the phasing directly at 2 meters, and then not have to worry about the extra stages? Certainly one of the advantages of the phasing system is that you can easily generate the signal directly at the output frequency. That would be extremely difficult with a filter SSB system, if you want to operate on more than one frequency. And no matter what frequency you use to do the phasing generation, the quadrature hybrid could be an interesting way to generate the 90-degree RF phase shift.

Best wishes on a successful project, no matter how you decide to do it. I'm sure you will learn a lot along the way.

Cheers,
Tom

I recommend the mini-R2 project. It's smaller, simpler, and a bit
easier to build. You can also achieve better opposite sideband
rejection with it. Some builders report 50 dB of opposite sideband
rejection with just a little effort at matching parts and setting
gain.

Kanga US sells kits for this project that might save you a lot of
time. It's worth a look. I'm just a satisfied customer. You can
find them at http://www.bright.net/~kanga/kanga/kk7b.htm

They also sell a board called the LM2. This was also outlined in a
QST article some time back. It is a tunable VXO with multiplier
stages to take it to 144 MHz. I'm in the process of building one now.

This kind of setup was designed to go directly to two meters. It
makes an excellent IF for microwave converters and the like.

>i am also working english (us) langage , school is a long passed time (

OK, I give up... how do I attach a solder type BNC connector to co-ax? Is there a site with pictures to guide me through? I've just got the loose components in a little bag. main body, a washer, a rubber washer, a small pin, and a cone shaped washer all (supposedly;y) held together with a threaded collar.
Soldered the pin to centre conductor, but where the braid is attached, pinched, secured is a mystery. I've had several attempts, all successful electrically but terrible when it comes to mechanically. They just don't stay on!! Is it just me or is there an art to these bloody things!!
A search with copernic produced lots of info about the crimped version but nothing on the solder version...

Les

Hello everyone,

I've recently come across a design for a resistive 50 ohm broadbanded RLB from Gyula Nagy, HA8ET, and am curious about a few things those with a more engineering mind might help with.

You can see it at:
http://www.pollak.sulinet.hu/elektro/hidak/bridge/how_to.htm

In particular, I'm interested in a device with a low drive requirement. The designer says the minimum drive is 100 mw with 1 watt (!) being typical. That just sounds high to me. I'd rather have a device that I can use a bench signal generator and not worry about having to develop 100 mw of drive at whatever frequency. This isn't so much of a problem in the ham bands of course, but my interests go beyond those frequencies and I'd rather not have to develop (or radiate) that much power there.

Is the limiting factor in drive level simply the sensitivity of the detector, or are there other factors at work here. The use proceedure in the above link asks the user to deliver 2.5 to 3 volts to the meter and read return loss from a precalculated table. Is is simply a matter of using a more sensitive scale (with less drive of course) and using the voltage change to loss formula? I realize there are losses in a resistive bridge design to overcome...how are these factored in to my question?

Thanks for your time...

Dennis

It's just a Wheatstone bridge (where the unknown may be reactive, of
course). You should be able to excite it with lower power. The limit
will be the level you can detect with the particular Schottky diode
you use. Using diodes designed for zero-bias detection work, I can
detect RF voltages down to under 100 microvolts. That takes microvolt
resolution with the meter, and at such low levels I think you'll find
it best to raise the load resistance on the diode's output circuit.
Anyway, you'll get (pretty nearly) the same output voltage for given
excitation and load SWR, no matter what the phase angle of the load
is, so you can get an idea of the excitation you'll need to supply if
you assume some minimum detectable RF level and some minimum required
SWR. So if you said you want to detect 1.01:1 SWR (which is below
what you'll be able to justify anyway...because you won't know the
impedance of your line that accurately, and the resistors you use in

the bridge won't be that accurate at HF, most likely), that would be the case if Rload = 50.5 ohms. You can work out the voltages: on the left branch, the voltage will be 0.5000 times the input voltage. On the right branch, the voltage will be 50.5/100.5 = 0.5025 times the input. So if you put in 1 volt of RF, that imbalance would give you 2.5 millivolts of RF to detect, which is plenty. In fact, you could go about 25 times lower to about 40 millivolts of RF input, and you could still detect the output. That's only about -15dBm.

BUT...the problem is that the detector is nonlinear down in that voltage range, so you need some calibration. If you have a generator with calibrated output, you can do a calibration and then always set the generator to the same level, and you should have very close to the same calibration every time. Or, you can short the bridge output port and set the generator to give the same detected output level you used to do your calibration. I'd suggest staying with a bit higher excitation power, like 0dBm or +10dBm.

Lacking anything better to do the calibration with, you should be able to use 1% SMT resistors for loads. Connect the resistor so it's right across the end of a 50-ohm line...or perhaps across something like a PC-mount SMA jack, adapted to your output port...but make sure the lead lengths are vanishingly small so as to not introduce reactance. The SMT resistors I've measured seem to be fine across the full HF range. I'd recommend a range from maybe 10 ohms to a few hundred ohms; that should give you enough to work out a calibration. (I measured some out to 6GHz, and they aren't too bad even that far, though not good enough for a calibration standard.)

Would be nice to outfit the bridge with a balun and a full-blown phase and amplitude detector, and then you can read complex impedance instead of just SWR.

Cheers,
Tom

3140. Ten-Tec Triton II Station FS or TRADE - needs some work

Newsgroup: rec.radio.amateur.homebrew

For Sale:
Ten-Tec Triton II 100 watt HF station. In nice shape, and includes the matching power supply / speaker with built-in VOX option. Also has the CW active audio filter option in the radio. Includes photocopy manual and original hand mike. The radio receives but is weak. The front end is a common 40823 (40673) dual gate FET. I bought a new one from Mouser electronics and installed it and it did not help. I was then informed that it is a static-sensitive device. I took no precautions so I probably fried the FET. Anyway, it has the calibrator, the dial has been restrung, it has new dial lamps, and the transmit puts out around 75 to 80 watts. The power supply is fine. I am tired of fooling with it. I bought it off eBay and thought it would just need an alignment. I paid $125 plus shipping for this outfit, have put another $35 in parts (+ shipping). I will take any REASONABLE offer that minimizes my losses or would be open to trades. I am interested in QRP and finding another Yaesu FT-7, HTX-100 or maybe an HW-8 radio. Shoot me an email with an offer.... I have the original eBay picture.

I will be on vacation from May 2 to May 12th. If you email me during this time please be patient.

Thanks!
Mark W4UDX

Bob,
I don't have an exact reference for that part, but I can tell you that it's an AM ceramic filter for a 455Khz IF strip. Can't tell it's bandwidth or impedance, but that's about all I can determine. I have a Toko catalog from 1986, and some scanned pages from a long long ago Toko catalog, but neither has that exact part in it.

>I assumed you'd want to do it directly at 144MHz; otherwise, why talk
>about 2m? If you do the generation and detection at an IF frequency,
>then the RF part is just mixing and linear amplification.

If you have a reasonable way of generating and detecting the SSB signal at the final frequency, why convert the signal with a large dynamic range and large number of signals to other frequencies. It is much easier to multiply, translate and filter a constant amplitude single frequency local oscillator signal chain to the desired operating frequency.

At VHF/UHF an opposite sideband rejection of 40-50 dB is often more than enough, since on receive you are usually interested in attenuating the opposite sideband noise (to get a 3 dB increase in S/N), while on HF, a quite good opposite sideband suppression is often required to attenuate strong unwanted transmissions.

Of course there are problems with the gain distribution and stability and the 1/f noise at low audio frequencies in the receiver audio preamplifier.

If some digital signal processing is available, why not operate the I/Q demodulator as an image rejection mixer feeding the wanted signal around say 10 kHz, in which case the 1/f noise has been reduced and the gain distribution is more even and with two digital channels, also handle the 90 degree audio phase shift using Hilbert transforms.

It seems that a lot of commercial products up to at least 2.5 GHz are currently built around various "zero-IF" approaches, just wondering, why this approach has not been more popular in various amateur devices at least in VHF/UHF. For HF the signal handling/dynamic range specifications might not be good enough.

I would agree that it is an integrated I.F. transformer/ceramic filter. In my infinite wisdom, when I got the current Toko databook, I threw out the old one that used to have that filter. The old Johnson solid state CB radios, such as the
Model 123A used that filter. I would almost bet that it has a yellow core.....maybe not. I better not bet. It probably has a +/- 3kHz bandwidth (AM).

Hi Duncan,

Unless there is soem sort of external requirement, is there any reason why you couldn't use a straight forward LC oscillator of a suitable stable design?

That way you'd have the ability to shift around a bit in frequency. If you keep the span of the tuned circuit small, there shouldn't be many 'netting' issues. I guess costs might be an issue for the tuning caps, though....:-(

Hi , Tom ,
Englih langage is not very difficult to learn , it is a universal
langage , in China, Tawain, Japon , ..
they learn english langage like second language , French itoo.
I think this due to old circum naigators like Cook , Marco Polo, Spanish
, Portuguese etc ...
This is a great luke , many people can speak with facility ....
There is esperanto but it is not well known by majority .
about TX 144 : look at this web link and speak about it around you , it
has a very good sound , very good stability (xtal rocks) , and i know
this friend , it live in Nantes (France) :

http://perso.wanadoo.fr/jacques.legoff/kits.htm
(transceiver 144 Mhz) with xtal filter homebrew .
each xtal (8,xxx MHz) about 25 dollars US + shipping
each band is 200 KHz , so we can heard 144,000 to 144,xx with x xtals
the vfo is a VXO
the others parts are not expensives , some neosid filters , etc .....
i have seen and heard it in working and this is a very good job for a
homebrewer .
some Franch OM have very good web site , look at :
http://perso.wanadoo.fr/f5cau/
i know many others web links like this
Good luke
Serge /f5jtm
i don't speaking today with a phasing exiter , because i have take a big
head about this , and i need some holidays for ....
the web site of K0JD is a good start .
73's
Serge

I'd like to build a VHF (6m or 2m) SSB radio. I'm most interested on VHF at the moment because of my license class, but will probably also want to build an HF radio sometime down the road.

And, while I can actually tell the difference between a resister and a battery, I am clearly not an expert at electronics. So this project will also serve as a learning experience for me.

Given the above, can you recommend a good book, again oriented towards the beginner, on home brewing a VHF SSB radio?

Your suggestions are truly appreciated.

If you are really as raw a beginner as you claim - perhaps you should
consider a kit?
The good ol' guys from MFJ come to mind. No gee wizz performance but not a
heap of junk either - Also very reasonably priced.

Hi,
Try looking at the Ten-Tec line of products they have radios,transverters
(converts 2M to 6M any mode).
Most of what Ten-Tec sells is kits .

Hi Dwight,
Unless you already have a LARGE amount of RF design knowledge, homebrewing an SSB rig (and VHF at that) is not feasable. Look at Hand Products- they make a 6M SSB kit- even these will require good soldering skills and good tools.

Hi Dennis;

I built the RLB that W1GHZ described in QEX and it works fine on
2.4 GHz with <15mW of drive. I have some extra 50 SMA termination
resistors if you need some...

Message-ID: <2bTra.1416$IU2.2050495@kent.svc.tds.net>
Source record: 35662

Hi All,
Is there anyway other than re-programming EPROM'S to make two devices communicate serially when one device is 4800, 8, N, 1 stop bit and the other is 4800, 8, N, 2 stop bits?

Neither micro that controls the devices can be re-programmed so both are stuck 1 vs. 2 stop bits. Is there a hardware or some other type of conversion I can try to get the two pieces of equipment to communicate?

Thanks,
Jeff

If the 2 stop bits device is the only one transmitting then the other can handle the bit stream, you just lose time since it will ignore the extra stop bit, async communications will ignore extra bit times.

Is this hookup just for a short time, to swap programming or files? A simple short term fix would be to hook them up to a comp with 2 free serial ports and then use software to link the two ports. An even more expensive method would be to network two comps together and then hook the devices up to to a computer each, since that only requires one free serial port per comp.

Back in the old days of uarts you could sometimes snip a pin and pull it up or down to select word length etc, but with the advent of vlsi all that is kept in internal registers now.
thanks, John.

Are you sure it was a 6AR11? That's a dual semiremote-cutoff pentode.
Not a tube I'd really expect to see used in a single-tube receiver.
The radio that the other reply linked to uses a 6AF11
(dual-triode+pentode). Probably a good chance that was what you saw.

Signetics 1974 data book list the N1004A as an ECL II series, dual 4 input
gate. It also states it is equivalent to Motorola MC1004P. Inputs on
1,2,3,4 and out put on pin 6 and compliment output on 5. other half is
10,11,12,13 input and out on 8, compliment out on 9. Tom WB6IQD

3165. Balanced ATU ?

The Denco coils is not made anymore, the only place I have seen them sold
lately is on E-Bay to very high prices. Here you can find instructions on
how
to make your own.

http://www.hanssummers.com/radio/transistor/intro.htm

You might be able to get the L210 from http://www.6v6.co.uk

Ten-Tec makes kits for that.

As a side note, the 20M -> 6M transverter kit
can be easily modified for 10M -> 6M for those who
have a 10M only all mode xceiver. Those 10M all mode
xceiver were popular a while back, and you can find
them at hamfests sometimes. I got one for $50.00
broken (a bad electrolytic cap in the audio amp) but
they usually sell for about $100 - $150. Works
great with the modified Ten-Tec kit.

I don't know how much real estate you have - but BG Micro
sells a 50 v 68,000uF cap - if you can go with 34,000uF,
put 2 in series. These caps measure 3.5" tall by 2.5" dia.
and cost $4.95 each. I know you don't want to go with
multiple caps, but my guess is 60,000 at 75V is going to be
hard to find.

In terms of home workshop resources, the HF range radio will
be a better starting place.

You need to define "radio" just a bit narrower. Receiver?
Transmitter? Transceiver? Converter?

> And, while I can actually tell the difference between a resister and a
>battery, I am clearly not an expert at electronics. So this project will
>also serve as a learning experience for me.

No one has to be an "expert" at electronics to do such homebrewing
but you must differentiate between true design, copying some article
from a magazine or book, or kit building. One DOES need to have
certain resources available in the home workshop (or someplace) for
any of the three levels: A reasonably accurate RF signal source for
receivers covering VHF; a reasonably accurate RF power output
measurement means for transmitters, also covering VHF.

For "learning experience," do what other suggest. Begin with a kit.
Kits have the advantage of someone else already doing the design
and proving the device can function close to what is advertised. If
instructions are followed explicitly, you will gain familiarization
with VHF techniques that are much more necessary than with
corresponding-function HF-range radios. Using supplied PCBs
there will be little difference between the original much-tested
design and final kit product, avoiding excess lead length and
excess lead inductance.

There are many different kits advertised in QST, QEX, CQ, and 73
for USA "learning experiencers." A web search will turn up most
of those. Communications Concepts has kits for solid-state
transmitters, essential components or full kits. Communications
Concepts had some VHF range transmitter kits but I haven't
checked to see if they still carry them.

> Given the above, can you recommend a good book, again oriented towards the
>beginner, on home brewing a VHF SSB radio?

Why SSB in particular? SSB at VHF is not for "beginners." Your
resources should include a reasonably accurate frequency

counter to insure you are operating stably and within band, both for the receiver and transmitter. SSB homebrewing needs some way to check modulation quality and make certain that transmitter modulation doesn't splatter out away from normal bandwidth.

Concentrating on solid-state amplifiers, a whole series of Motorola Application Notes done by Helge Granberg of Motorola forms an essential learning "book" that explains their particular techniques in great deal, including construction. Communications Concepts has/had some of those AppNotes available free on their website (pdf quality not as good as what was available direct from Motorola). Those amplifier AppNotes started appearing around the mid-1970s and continued for roughly a decade. Some were reissued with the same information at later dates.

You can find all sorts of amateur VHF projects in amateur radio publications in English, both here (principally from ARRL) and from RSGB. The one thing you MUST remember on copying those projects is complete attention to detail on all parts...at VHF and UHF all passive components have significant parts of parasitic resistance, capacitance, and inductance. Active devices have specific input-output impedance/admittance characteristics which were probably taken into account by the designers. You can't blithely swap another unfamiliar part number solid-state device for the one specified unless you KNOW what the substitute has and can do.

Kit building using supplied kit parts is the first step for learning VHF to UHF techniques. Chances for success are better there than starting off knowing just some differences between "resisters" and batteries. Jumping the gun to the next plateau of experience-knowledge is overly ambitious unless you want to spend (literally) years of your own time in self-learning needed to make your own design from scratch.

> Your suggestions are truly appreciated.

You may not like my suggestions. A common tendency is to look at some finished production-line product and say "I can do that" without thinking things through carefully. That finished manufactured product represents hundreds of hours of design and development time by many people who have "been there, done that" in going through their learning experiences. The same applies to some author's construction project, the author also with some "learning experience" over a long time. What you don't see are a LOT of construction projects that failed to perform and thus never got any write-ups.

Over-confidence is an easy attitude to adopt. After the first few failures you learn what doesn't work, at least in the way you did it. Self-education is necessary to learn what exists in the real project but was cut from the construction article, how to test something,

what you need for testing and development work. Eventually you get to real personal confidence after some successes. That point is the beginning of being able to truly homebrew something of your own...and to recognize what is practical to do and what isn't practical.

>Neither micro that controls the devices can be re-programmed so both are
>stuck 1 vs. 2 stop bits. Is there a hardware or some other type of
>conversion I can try to get the two pieces of equipment to communicate?
>
>Thanks,
>Jeff
>
If you connect the hardware handshaking lines, it may work, even though
the stop bits are not matched. One will not transmit until the other is
ready, and you will avoid the over-run problem when the '1stop' is talking
to the '2stop'. When the '2stop' talks to the '1stop' you should have no
problem other than a very slightly slower throughput, as you are idleing
during the extra stop bit.

Now, if it is a real problem for you, and you just can't get it to behave,
then perhaps you could build 2 back to back UART chips set with a 16X clock
input from a 555 timer, or a real clock generator, and set the hardware UARTS
to the desired data bits, and stop bits. I have done this back to back thing
several times. The chip I seem to remember using was something like AY-1013,
or perhaps AY-5-1013. It has been a few years, so I am a bit fuzzy on the
part number. I used them to convert 7 bit data streams into 8 bit, and back.

Best luck.

Jeff, hook them up and see whether they work. They probably will.

Normally, the 2-stop-bits setting only applies to transmitted characters.
On receive, the receiver SHOULD be able to cope with just one stop bit,
unless it is doing some really flakey non-buffering stuff and burning a lot
of time before it starts listening again.

Put a PIC between them... I have a PIC that receives 1200 bps and re-transmits the data at 300 baud. Shouldn't be too much trouble to receive 8N2 and xmit 8N2 or the other way around....

Could be why he said "series".
Problem is we do not know waht the end users operating voltage would be.
I believe the responding party had to assume that it could be above 50
volts. Of course there should be dividing resistors and the lot.

Regards

I'd say that the artifacts you're seeing are in your DSO. The AD9854's spurious signals should not be visible on a time-domain instrument except possibly at a very few worst-case frequencies that you're not going to stumble upon by chance.

What happens when you look at a clean LC oscillator at the same frequency?

>Normally, the 2-stop-bits setting only applies to transmitted characters.

It sets the character frame length for the receiver, and if that
length is not used by the transmit side the early start bits
will fall within the previous frame interval and be ignored,
causing the rest of the current frame to be garbled. The
receiver loses sync.

>On receive, the receiver SHOULD be able to cope with just one stop bit,
>unless it is doing some really flakey non-buffering stuff and burning a lot
>of time before it starts listening again.

If the receiver is set to 2 stop bits it had *better* be burning
2 bits worth of time!

Sending it a data stream with only 1 stop bit should result in a
series of framing errors, totally garbling the data output.

Actually, being 1 stop bit off is a *huge* problem! Twenty
years ago Infotron and others made various kinds of stat mux
equipment that multiplexed asynchronous serial data streams, and
these could be configured with stop bits incremented in
something like 1/8th of a stop bit. A 1/8th difference in the
receiver and transmitter was an interesting problem... it would
vary from maybe 20 to maybe 200 or more characters sent before
the receiver would lose sync. Where I saw this was on mux
equipment between Telex exchanges, so basically a very short
message might make it through, but most of them began garbling
in the first paragraph of the message body. Customers would see
just enough to know what they were missing... ;-)

I don't know about that. Even I can build one of those. Seriously, if you
want to see what it takes to design a receiver, check out my website at:
http://home.att.net/~n.gianakopoulos/wsb/html/view.cgi-home.html-.html
This receiver could be used up on the 6 and 2M bands, but it would be good
to add an RF stage ahead of the mixer. Also, you would need to change the
LO injection frequencies, and the input filter parameters.

That is very good advice. I remember my first dual-conversion receiver. I thought "no images anymore". You can imagine my dismay when I had only 35dB of (2 X 2nd I.F.) rejection. It turned out that radiation from the 2nd LO was creeping back into the 1st mixer, and manifesting itself in this way. It was only in desperation that I took some copper flashing and shielded the oscillator. At that point, the image disappeared, just like switching a light off. It gets even more critical at VHF/UHF ranges.
Anyway, a few other good books to get you started are the ARRL handbook, Ulrich Rohde's book on communications receiver design, and Solid State Radio Engineering. A good book on frequency synthesizers is "Frequency Synthesizers, Theory and Design.

That should be a workable item. I am not sure what the input/output impedance is, though. It seems that it was used in receivers that had bipolar I.F. strips. If you can find some of the Murata CFWS-455 series of filters, or their Panasonic, TDK, or Toko equivalents, these are pretty good. They have in input/output impedance of right around 2K, which makes them great for NE602 projects.

Hi Guys and thanks for the feedback.

>> >>>I need a pair of 75 WV DC, 60'000uF electrolytic cap's.

>> >>I don't know how much real estate you have - but BG Micro
>> >>sells a 50 v 68,000uF cap - if you can go with 34,000uF,
>> >>put 2 in series.
>> >
>> >
>> > Uhhh, gomer, capacitors in PARALLEL add.

I do in fact require a minimum working voltage of 75v and at least
60'000 uF.

I'd forgotten to check BG Micro.

Newark offer Vishay/Sprague 75v @ 60'000 uf but at $62.50 each, ouch.

After shipping here to the UK that would bankrupt me.

FYI they're for the PSU in a class-E AM rig.

I'll keep looking.

Tnx

I'm looking for the schematic diagram of the MFJ -9606 6m FM transceiver
(I've got the radio without any manual and I need to repair it).

Any help is appreciated.

Thanks !

Thanks for the suggestion, both Mark and Roger. However, I've already built many kits. And while I did learn a little from those kits, it was certainly not enough to build my own VHF radio without serious guidance. There are still simply too many gaps in my knowledge about electronics. In other words, I'm still a beginner in too many areas. Because of that, the books I've seen on radio construction lose me fairly quickly. Therefore, I was hoping for a book that didn't assume so much knowledge on the part of the reader. With that, I could probably muddle my way through to a fairly basic radio.

> power output measurement means for transmitters, also
> covering VHF.

Okay, perhaps I should have been more clear. Obviously, I have no desire to design a radio from scratch at this stage. I've done some kits, but was hoping to learn a little more. That leaves the book that doesn't automatically assume a certain knowledge level, yet takes one from a "beginner" level to a more complete understanding of radio construction (preferably using hands on construction of a actual radio to do so).

And, yes, in spite of taking several electronics courses, there is too much I don't understand to call myself anything other than a beginner.

That book is not as easy to find as one might expect. There are books designed for beginners that take one to a certain point with no guidance on what to do next. There are more advanced books that assume a starting knowledge level far beyond where those beginner books leave off. So, I guess what I'm really hoping for is a radio book that bridges that gap.

With modern day UARTs the receiver doesn't directly care how many stop bits there are. It will stay locked in the stop condition as long as the transmitted stop bit remains (1, 1.5, or 2 bit times). It is the start bit that causes the syncronization between transmitter and receiver.

Thanks all for the comments, but it will not work right now. The transmitting device is my repeater controller (4800, 8, N, 1) and the radio is the FT-1000D (4800, 8, N 2). The radio will not recognize commands from the controller. I have tried controlling the radio from the computer where I could change the serial port to 4800, 8, N 2 and it worked fine.

Looks like it just may not happen.

Thanks,

Jeff W8CQ

You might want to look at the Electronics of Radio by
David Rutledge, which is designed to teach Caltech
students how the Norcal 40A works (40M CW
transceiver). It does assume a good knowledge
of math/physics, but I think it is unreasonable to expect
a radio book to teach you everything.

Experimental Methods in RF Design by Hayward,
Campbell, and Larkin does have 6 and 2M transmitter
designs. They present the three most popular methods
of generating SSB--by filtering, phasing, and DSP.

I've written up a 2M SSB/CW transmitter and receiver for QEX,
which may be published in the next few issues. Scheduling can be difficult
to predict, especially for longer articles, as they like to use my column
to "fill out" the magazine.

I've been soldering them for years, but I still find a soldered on pin and crimped screen is better (if the leads are later used by non-techies).

OK, the problem is that you have to learn to walk before you can learn to
run.

If you've built kits, then the next step is building from a schematic and
parts list. I'd suggest "W1FB's Design Notebook" by Doug DeMaw W1FB/SK, as
a good starting place. He gives several simple designs, in schematic form,
and has some good suggestions on construction practices. Also be reading
"Solid State Design for the Radio Amateur" by Doug DeMaw and Wes Hayward
(nominally out-of-print but still easily available from lots of places).

Plan on doing your earlier experimentation at HF rather than VHF. You can
get away with murder at HF and things will still work. VHF is not so
forgiving. There is a LOT of stuff to be learned before you can design your
own VHF rig.

It can be done, but it will get a bit ugly. You'll need a data buffer
between them, taht takes the data at 4800-8N1 and translates it to 4800-8N2.
This will require some RAM for a buffer. Check with your local ham and
computer clubs; there's bound to be at least one microcontroller nut who can
hack something up for you.

The newer BNCs are not "crimp - on". They are "twist-on". I've used a few - at first with hesitation as I didn't like crimp ons either. But one day, didn't have a choice. Found them to work rather well. NONE of them has given me any trouble - yet. Strip the wire as shown in "simple instructions" and twist it on. Whalah, connection made. Don't knock it until you try it. I like these especially when making up different test cables. Don't have to heat up an iron to whip a good cable together. If the cable breaks say from stress, unlike a crimp on or solder on, you just unscrew this, trim cable back, strip and reinstall. Would I trust one for a prolonged and uncertain environment? Not sure; but for all else, seem just fine. Just my opinion.

(snip)
Why a SSB radio? While there is some activity on VHF SSB, it is tiny
compared to HF SSB. Aside from VHF/UHF contests a few times a year, most
VHF/UHF SSB is *very* local. If there is any activity at all in your area
it may only be one or two nights a week. Some places have virtually none.

Maybe an FM radio would be better?

I concur with John completely. I'm currently at the stage where I'm designing
and building HF stuff and scratching my head when it doesn't do what *I* think
it should be doing. It's humbling, to say the least. The Radio Amateur's
Handbook and Solid State Design for the Radio Amateur are two must-have books.

My suggestion is to get a copy of LTSpice from Linear Technology - http://www.linear-tech.com/software/. The price is right. ;-) I like to design
a stage, simulate it, and then mock it up and see how far off I am. Then I try my hand at tweaking to get closer to the simulation. I'm looking forward
to designing VHF, UHF, and microwave hardware, but I'm definitely not there, yet.

Hi, has anyone built the doubly balanced mixer described in this QST article? How well did it work? The article appeared in June 1987 QST p. 30, and was re-printed in 1990 in "QRP Classics" p. 45.. Don't have the QST, but have QRP classics.
There is an error in Figure 2, Fig. 2(A) the schematic and Fig.2(b) physical wiring do not agree. Transformer T1 is wired incorrect in the physical drawing. I was going by the physical drawing when I built mine and could not get it to work. I found the problem, but that was as far as I got. Before I dive back in, I would like to know whether it is worth my time. (I got a little irritated when I found the error).

On a self-education sort of project without actually building
something, I'll suggest one way to improve yourself with
knowledge.

First, envision a real project and then block out the different
sections of it. Set up some kind of specifications as a
guideline. Study each block and ask yourself if you are
familiar with a typical circuit in that block or not. If you
aren't familiar, that's one area for self-education.

Take each block and flesh it out to a circuit. You don't need fussy details here, just enough to present some kind of circuit that might work. Are you familiar with details within that circuit or not? If not, that's a learning area.

You keep on going like that until the whole whatever is taken down to the component value in detail.

Individual blocks might be done in several ways. Think about all the kinds you've seen done, check the books to see if there are different ways to do it and try to find out why it was done that way instead of a more familiar way.

All the blocks have to interface with one another...and so do all the smaller blocks within a larger block. Even though "interface" is an over-used word, it applies generically here. If the blocks can't work together, the whole project won't work well. Optimum power transfers always require matching of some sort. Do you understand matching? If not fully understood, that's another area for more self-learning.

Not everything in a book's schematic is fully represented at high HF, VHF and above. There are "stray" capacitances, inductances, resistances in many places that aren't on the schematic. Many of those are INSIDE semiconductors and "appear" only as notations on datasheets in complex arithmetic form. Are you familiar with complex arithmetic notation and their equivalent circuits? If not, another learning area. You MUST be familiar with it to make resonant things at VHF and above.

You might need some filters some place. Do you know how to make basic types of filters? Are there Q requirements for those components to achieve a desired response? Do you know what you need in basic stopband attenuation in those filters? Can you accurately measure the response of a filter once it is completed? Do some of the component values need trimming but others can be fixed? Could you make one with all fixed values within tolerance range? The latter condition requires some simulation with an analysis program to avoid wasting lots of hours of cut-and-try on the bench.

If some blocks require frequency shifting, do you know different mixer types? Do you know about image responses? [image rejection may dictate filter stopband requirements] Is the "conversion gain" adequate in a mixer (passive types have loss, a negative gain)? How about intermodulation distortion and intercept points and their values?

Can you outline the "gain budget" in a receiver over all stages? Are the signal levels too high in back-end stages at maximum expected signal inputs? If so, how can you compensate or avoid distortion from overdriving those stages? If you need

very low noise levels at the input, do you know the "Shannon Laws" relating noise, bandwidth, and information rate? Do you know which circuits are low-noise, which are not low-noise at input stages?

On transmitters you need to set up another "gain budget" from the final amplifier back to the beginning stages or blocks. For Class C operation that gain budget can be relatively loose but Class B or AB need more attention. Typical SSB finals need B or AB stages. What are the effects of overdriving and or distortion? How can you correct that? What circuits would yield best linearity? Do you need narrow, medium, or broad band operation in the transmitter? That choice will probably dictate the final-to-antenna matching for best signal output. Bandwidth also dictates stage-to-stage matching, tuning.

On frequency control, how far do you need to tune and at what stability? A single quartz crystal off the shelf is typically +/- 50 PPM tolerance to a given frequency. Is that close enough or do you need it tighter? [50 PPM is equal to 0.005%] Can you make do with continuous manual tuning a la VFO? Or do you need lots of "channels" at fixed intervals? [PLLs would be good for that] Do you need continuous, small-increment tuning with quartz stability? [usually calls for DDS or an involved multi-loop PLL] Will this frequency control apply to both Rx and Tx? If so, are there automatic changes of frequency between Rx and Tx due to IF offsets and such?

Do you know basic Phase Locked Loops? Can you make a typical VCO or Voltage Controlled Oscillator? A divider chain that is adjustable for IF offset and others? A phase-frequency detector? The all-important Loop Filter and its calculations? Do you have a way to check and test the frequency and stability of the final PLL?

PLLs are quite "clean" in output compared to DDS and the Fractional-N types of frequency synthesizers. The DDSs are not really beginner areas and should have some kind of spectrum analyzer available to see what the spurs are and where in frequency. If you want a DDS type, do you know how to design it for minimum spurious output and how to correct that or what such spurs might do to other blocks?

After all of the above, you've got to supply operating power to all those blocks, have to know their voltage and current requirements. Are you going to operate from AC mains or from batteries? Do you need some regulation, lots of regulation of voltage? Current regulation? Do you know the worst-case limits of the primary power source? Energy storage capability in batteries? A way to recharge the rechargeable batteries? Can you get by with series regulators or do you need "buck" or "boost" supply circuits?

Do you know how to handle filtering in power supply distribution? Can you avoid feedback or effects of any kind between blocks? Can you select the right kind of bypass capacitors for decoupling at the frequency ranges desired? Do you need high efficiency in the power supply or can you get by with lower efficiency? If powering an on-off keyed final or SSB final running B or AB, can the power supply handle rapid load swings? Will those load swings reflect as supply voltage changes to driving stages?

That's a whole potfull of questions, isn't it? Nearly all of them will apply to HF transceivers and some VHF transceivers. Each and every designer goes through similar "checklists" since they all have a relationship with the finished project.

I haven't mentioned the embedded microcontrollers so common in ready-built transceivers and receivers today. Those have their own prodigious set of questions that need answers.

You, as a designer, whether of a real project or just trying to learn how it can be done, don't need any formal education in engineering to do all of that. The information IS available in paper, lots of it on the Internet. It isn't all in one convenient place or one book. Some books DO come close. It is hardly found in "primer" form. You are going to have to contend with ordinary algebra and trigonometry to get cozy with the concepts, to understand what is going on. You must get to know complex number arithmetic (made up of ordinary algebra and trig) and how impedances/admittances have equivalent circuits at one frequency.

You do NOT need calculus, sheepskins (unless you like them in your car), formal education, extension classes at a school unless you want to hurry-up the education process at the expense of time away from what you want to do elsewhere.

There isn't a single electron, field or wave that is impressed by someone's certificates, titles, academic letters behind the name, or any human emotion. YOU have to be the student of what those electrons, fields, and waves need to make them behave. Learning that happens the same whether in a formal classroom at 2 PM or at 11 PM in the quiet of a room at home. All learning happens inside an individual's head, nowhere else.

Other than that, this theory and design stuff is straightforward. :-)

Well, I just grabbed the first data sheet I came across - The Philips SCC2691 UART. I quote "The receiver only checks for a mark condition at the center of the first stop bit". Earlier it states that only the transmitter is affected by the stop bit setting.

If you think about it, what is the difference between one stop bit followed by a constant mark (i.e. no further data) and two stop bits? Now it may be in the case of the FT1000, it is not using a standard UART chip or that there is some issue with the processor not getting back to read the UART in time unless it has the extra delay of the second stop bit. As far as most UARTs themselves are concerned it makes no difference if there is one stop bit or one-thousand.

3215. 10.5 Ghz microwave emitter source

Hi. I hope someone out there can help me. I am trying to find a place to get a 10.5Ghz microwave emitter. I understand that broken radar detectors and those motion sensors found on automatic doors are great sources, but I can't seem to find any. Does anyone know of a place or places that I can find something like this? I've searched website after website and scoured the newsgroups, but am still at a loss.

Thank you very much for any info you can share.

OK, you have one UART which does that. Your statement was that
they *all* do it.

Personally, I think it is a design short cut, and an
abomination. :-) There is no immunity to a false start bit
occurring within the last 1 1/2 bits of the stop bit. That can
increase the error rates in the presence of noise.

The immunity to a false start bit comes from testing for the width of the start pulse. If it gets a space it delays 1/2 bit time and checks to see that it is still a space. If not, then the counter is reset to wait for another space. A noise pulse would have to be at least 1/2 bit time wide to cause a false start trigger. At least that is how it worked on the UARTs that I have written code for. I should never say all because there is always the exception - I'll stick with most :-)

Obviously that can fail miserably if that particular UART is set to
2 stop bits.

You can fit at least two false start bits between the 1/2 bit
test point and the 2 bit end point of the stop signal.

They will be accepted as a start bit if the frame interval is
not timed.

You did not answer the question about a second method to test the validity of a start bit.

Bit asynchronous (or isochronous) data streams do not necessarily consider a frame interval. If the condition exists wherein frame interval is to be considered, then you have a data stream that is not structured for the async or isoc bit mode.

Uncorrected bit errors can occur at anytime when forward error control is not used. The statement that "...two false start bits between the 1/2 bit test point and the 2 bit end point of the stop signal..." can just as easily be applied to bit one, bit two, bit three etc. as to the stop bit.

If in fact a two bit wide error occurs, then that is exactly what you have...a two bit error. And that happens whether you have one or two stop bits assigned. If test/wait/test detects a start bit, then in all probability you have a start bit.

Without considering special conditions wherein a two bit time interval between data words is expected, a one stop bit system will talk to a two stop bit system without error. Maybe not so in the old days when you had mechanical systems that needed 'additional' time to stabilize between data words.

Yes I did. Early start bits are detected. Sorry if I didn't
make it clear that that was what I meant.

>Bit asynchronous (or isochronous) data streams do not necessarily consider a
>frame interval. If the condition exists wherein frame interval is to be
>considered, then you have a data stream that is not structured for the async

Asynchronous data is character framed, by definition.

We are not discussing isochronous data streams. Framing is
entirely different for an isochronous data stream, because that
is by definiton async data send over a synchronous link. (That
is an unusual topic, and anyone who wants to know what the heck
I meant by that... just ask and I'll explain it in more
detail.)

>Uncorrected bit errors can occur at anytime when forward error control is
>not used. The statement that "...two false start bits between the 1/2 bit

>be applied to bit one, bit two, bit three etc. as to the stop bit.

The difference (and BTW, I was wrong, it would only be 1
possible, not 2, depending on how the stop signal interval is
tested), is whether a single (uniquely defined and uncommon)
burst of noise takes out one charcter maximum, or two minimum.

>If in fact a two bit wide error occurs, then that is exactly what you
>have...a two bit error. And that happens whether you have one or two stop
>bits assigned. If test/wait/test detects a start bit, then in all
>probability you have a start bit.

With (assuming 8n2) a noise burst causing random mark/space
transitions that extend more than 1/2 bit but less than 1 bit
interval into the stop signal, it can cause an error in that
frame, garbling a single character. That of course is if the
frame interval is timed to 1/2 the stop signal width (1 whole
bit time interval).

If only 1/2 a bit time interval (1/4 of the entire stop signal)
is timed, that same noise burst will error two characters and
cause a loss of synchronization until the transmit data has a
pause long enough to allow resynchronization.

Probably the most significant part of the difference is that in
some (relatively few to be sure) instances a noise burst that
would error a single character will instead cause a loss of sync
(at machine speeds... we aren't talking about a link that has
timed data or someone pecking away at a keyboard).

>Without considering special conditions wherein a two bit time interval
>between data words is expected, a one stop bit system will talk to a two
>stop bit system without error. Maybe not so in the old days when you had
>mechanical systems that needed 'additional' time to stabilize between data
>words.

Mechanical systems didn't! On an old TTY machine, as soon as
the clutch stopped the shaft rotation, the shaft would be
immediately started by any detectable space condition. No test
for validity of start bit timing was done at all. The stop
interval wasn't timed either, and either that clutch stopped it
as it came by, or it didn't, as there was no test to see how
long the stop signal lasted any more than one to see how long
the start bit lasted.

But that didn't time between words. It timed between characters
to allow different frame lengths cause by different data rates.

The 1 1/2 bit intervals for the stop signal allowed for
different shaft speeds, and hence data rates, on the transmit
and receive machines. That was originally quit common when DC
series wound motors with a governor were used, but only a very
out of adjustment machine required extra time with a
sycnchronous AC motor.

The advantage that electronic circuits have is good enough
timing that not only can they work with only 1 stop bit, they
don't even need that much. Stop bits of 3/8 of a bit work fine
if both ends have even a fairly good clock source and only
normal amounts of jitter.

In addition, electronic circuits can test for both the start and
the stop bit being at least 1/2 the desired length (i.e., less
than 100% distortion), and lock up in mark hold looking for a
new start signal to synchronize to if it isn't found.

I thought it interesting to hear that someone had actually hard
wired a system with 2 stop bits, because frankly I don't think
I've ever heard of anyone using it for anything other than
sending to a mechancial TTY (which is why a UART that ignores
stop bit length on receive can get away with doing that, because
otherwise in this usage the tx and rx configurations would have
to be different).

3226. Re: Beginner wants to build VHF radio - book recommendations?

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-05-02 13:24:05 UTC
From: Richard Hosking <richardh@iinet.net.au>
Message-ID: <3eb27190$0$26943@echo-01.iinet.net.au>
Source record: 35729
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment,alt.ham-radio.vhf-uhf

As others in this thread have pointed out, you have chosen a challenging task.
I presume you are a novice and unable to access the HF bands. I have never understood this requirement - I suspect the full licensees wanted to keep HF to themselves :)
I have always found the first challenge to designing radio gear is to have good test equipment to see what is going on.
In the end I have given up designing the radios and just had fun working on the test gear :))
Ideally you will have a spectrum analyser, a decent CRO and a good sig gen - say a HP8640B. I presume you dont have these
(Many of the "experts" will though - they know it is almost impossible to do serious design work without them)
Other equipment would be a multimeter, HF receiver and homebuilt units such a s a noise bridge, return loss bridge and signal source.

I suggest
as others have pointed out - adopt a building block approach, and wherever possible get rid of variables that you can control, so that you know what the final result is.
Use good design practice with lots of bypassing, short leads and ground planes so that you know the circuit will not be unstable due to these factors
Start with a current limited, regulated power supply with voltage and current readouts
Do the easy building blocks first.
For an SSB rig I would generate the SSB at HF (say 10.7 MHz for 2M) and look at the result with an HF receiver and/or CRO (it should be possible to get hold of these cheaply)
I would consider the use of surface mount components. At VHF they are much more predictable and the techniques for SM are not too hard to master.
I would consider an FM rig rather than SSB as it is probably easier to design and there are likely to be lots more people active on FM than SSB in your local area
You might be able to get a surplus FM rig that can be modified to amateur bands if you dont want to build your own.
You can reduce the RF design by using "block" filters such as helical filters which can be got from specialist suppliers.
In the end, the hard part is knowing whether your oscillator is working when you have nothing to look at it on.
Start with a reciever - you can hear local repeaters if the LO is working.

3227. Amplifiers with Untuned Inputs

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-05-02 14:29:17 UTC
From: ^2@vc.net
Message-ID: <^2-02050307291700001@192.168.1.200>
Source record: 35730

HF g-g amplifiers such as the Dentron MLA-2500, Heath SB-230, 374, ETO 78, and 76PA have no tuned input. This is not a problem when such a g-g amplifier is driven by a tube-output radio such as the TS-830S. The reason is that although the input Z of a cathode-driven triode fluctuates from roughly 1/3 of the average driving Z on negative peaks to a virtual open circuit on positive peaks, the Pi-network tuned circuit in a tube-output radio acts as a flywheel to smooth out the wild and crazy Z fluctuation at the cathode/s. However, with modern solid-state radios there is no tuned output, so something is needed to smooth the Z fluctuation. A possible workaround, short of adding a bank of tuned input circuits, might be to put a ultra fast recovery diode in series with the input terminating R. The diode is oriented so that the terminating R conducts only when the driving potential is positive -- which is when the tube is not conducting.. Thus, on the negative half of the driving cycle, when the tube has a low driving Z, no driving power is lost in the terminating R and the driver should see a lower SWR.
- - Unfortunately, I do not own such an amplifier to test the idea on. If anyone out there has such an amplifier and is willing to test this idea and report your findings, please inform me and I will send you a freebee 35nS, 2A, 300v switch diode.

thanks

I want to build a PIC based ctcss unit for use in my Yeasu handheld.
It was designed for the FTS-12 ctcss unit but those are no longer
made. At this point I am looking for any info on the FTS-12. It looks
like the micro in the radio sends the FTS-12 serial data that relates
to the tone frequency it is supposed to generate. Any idea what that
data stream looks like? TIA

<< I saw a picture of a balanced ATU once that used
a balun made from RG58 turns on a former, >>

Mike-

When I read the title of your message, I jumped to the wrong conclusion. What you really are describing is an unbalanced ATU that uses a BALUN to achieve balance.

While there may be an efficiency advantage of a co-ax over a ferrite BALUN, the difference is usually not great. If I were doing it, I'd go for a good ferrite BALUN. Your project must be for QRP, where every milliwatt is important!

Have you considered an ATU that has balanced output without use of a BALUN? In years past, such tuners were available commercially. An example is the Johnson "Matchbox", which has a symetrical tuned circuit with center grounded. You may find home-brew plans for such a tuner in old handbooks from the 50s and 60s.

Message-ID: <i5o7bv8pbegff3uukp01bqn3olt8r15rbk@4ax.com>
Source record: 35735

I'm trying to do some homebrew 10 ghz.
ARRL has two files I'd like but they say for "members only".
I'll become a member as soon as I get my license later this summer.
But I'd like the pdf file now.

1. Gunnplexers (144,130 bytes, PDF file)
2. Periscopes for Microwaves: 10 GHz without Feed-Line Loss (1,158,773 bytes, PDF file).

http://www.arrl.org/tis/info/microwave.html

If someone could grab one or both those files and send to:
kr4495@attbi.com
I'd really appreciate it! I just don't want to join till I'm sure
I get my license. It's a matter of timing.
I join them bigtime when I pass my test.

Thanks for any help.

3235. Tx filtering

Newsgroup: rec.radio.amateur.homebrew
Date: 2003-05-03 16:10:21 UTC
From: hamish@cloud.net.au
Message-ID: <3eb3e9ed$0$15598$afc38c87@news.optusnet.com.au>
Source record: 35738

Hello,

I'm building an HF linear amp of around 300W and I'm currently considering the issue of low pass filtering. (I expect the amp itself will be based on the Motorola AN758 -- http://www.communication-concepts.com/an758.htm)

Firstly, is it correct that a push-pull amplifier will only have odd harmonics and not even? Will the intrinsic suppression of these harmonics be sufficient or will they need external filtering?

I'm trying to minimise the number of filters (and relays) needed.
If it's not necessary to filter the second harmonic, then I think I could get away with one LPF just above 10.2 MHz for 80/40/30m, and another just above 30 MHz for 20/17/15/12/10m. (I'm ignoring 160m here; that would require one more filter.)

Even if I did need to filter the second harmonic, I think I could get away with 80, 40/30, 20/17/15, and 12/10 for example.

Is this feasible, good practice etc? Critical comments welcome.
I saw some photos of homebrew solid state amplifiers on the web with 6 LPFs in the output, so perhaps there's good reason. But I'd prefer to save the money/space/effort if I can!

Finally, any suggestions on a source (online probably) for RF relays rated to 300W? High coil voltage is fine, the amp will be running from 48V.

Thanks,

Hamish

Source record: 35739

Gary,

Hot carrier diodes work a little better than Si at HF and work a lot better at VHF. This discrete style of building mixers will give good performance comparable to commercial DBMs if you do a good job of construction. Depending on frequency ranges and signal strength core choice and size could be played with to optimize performance. Also, number of turns may show some differences in performance. Start with DeMaw's suggestions and see what you get.

I have never trusted DeMaw's designs or his documentation. His published stuff is frought with errors in the schematics. I also think he was a tinkerer and when he got something to work for him, he published it, without ever spending a lot of time seeing if it could be duplicated. He did have pretty good craftsmanship, though and his finished work always looked good. His oscillator designs are hit or miss, for example. Lots of people who have tried them say they drift all over the place.

This DBM, however, is pretty tried and true, except for the diagram error you noted. Should work FB.

Actually it is very useful to belong to both your local ham radio club and
the ARRL if you have any interest in ham radio even if you don't have a
license. I've known people who were members for years but for whatever
reason did not pursue getting ham licenses.

That spectrum analyzer is an especially handy tool. It not only allows you to see the spectral purity of your oscillators, but, when used with a noise source, it allows you to see the frequency response of filters. I have just such a noise source design posted up on my website. It is a modified version of the ARRL circuit, but with RF amplification following the noise diode, so you can have about 0dBm of RF power across the spectrum.

Pete

Mike,
A balanced antenna of the type you want to build was in Feb. 1990 QST. It used 10 meters of 50 ohm coax wound on plastic pipe 5 inches in diameter. A two liter soft drink bottle would do. The balun was used on the input side of the tuner. I think the author has a web site with the article on it, and has been spotted on this NG.

An FM transmitter is much simpler as it can be crystal controlled and
same for the RX.

Building a SSB transceiver for 6 or 2m is as many said not trivial,
I've built five but then I'm also an engineer. I also have a BIG
junkbox.

MY suggestion is build a kit or two and understand them first. Then
try a simple TX maybe CW then with some of the mentioned books and
a handful of old ARRL Radio Amatuer Handbooks you may embark on
experimentation. To be successful you will need good basic test gear
and fully understand how to effectively use it. The latter is very
important as now matter how good your design you will find a miswire
or bad part will require troubleshooting. Being able to fix a radio
is an important first step if you going to experiment.

Indeed it is. Also expensive to purchase and you have to understand
it to make sanse of the results. Building one is nearly as complex as
the SSB tranceiver task.

An aside, while I've had access to one I've done a large amount of
design and construction without it. There are ways to evaluate
circuits without a spectrum analyser. A good book on exactly this is
Experimental Methods in RF Design ARRL costs 35$ but is a excellent
reference and has a lot of already published work in one place. It's
also rather light on math for the phobes.

Push-pull provides some, but (IMHO) not adequate harmonic
suppression.

I would use filters designed to cut off comfortably above each
desired band of operation, but capable of providing good
suppression of the 2nd harmonic in their own right ... there's
no such thing as a "too clean" signal :-) (though I recognize
the desire to keep size/cost/complexity down as well ...)

POSTED AGAIN BECAUSE OF SERVER PROBLEMS - SORRY IF APPEARS TWICE.

Thanks for the suggestion, both Mark and Roger. However, I've already built a few kits. And while I did learn some from those kits, it was certainly not enough to build my own VHF radio without serious guidance. There are still simply too many gaps in my knowledge about electronics. In other words, I'm still a beginner in too many areas. Because of that, the books I've seen on radio construction lose me fairly quickly. Therefore, I was hoping for a book that didn't assume so much knowledge on the part of the reader. With that, I could probably muddle my way through to a fairly basic radio.

To answer your question, Avery, transceiver or receiver/transmitter pair.

Okay, perhaps I should have been more clear. Obviously, I have no desire to design a radio from scratch at this stage. I've done some kits, but was hoping to learn a little more. That leaves the book that doesn't automatically assume a certain knowledge level, yet takes one from a more "beginner" level to a better understanding of radio construction (preferably using hands on construction of a actual radio to do so).

And, yes, in spite of taking several electronics courses, there is too much I don't understand to call myself anything other than a beginner.

That book is not as easy to find as one might expect. There are books designed for beginners that take one to a certain point with no guidance on what to do next. There are more advanced books that assume a starting knowledge level far beyond where those beginner books leave off. So, I guess what I'm really hoping for is a radio book that bridges that gap.

I'm prepared to spend a reasonable amount of money to purchase the equipment I'll need. Assuming I don't have to buy the most expensive of everything, nothing in the equipment catalogs shocked me. I also have some minor experience with various test equipment.

Thanks for the various suggestions. I'll keep them in mind.

Actually, my first idea was to purchase a basic SSB kit and try building it up from there by adding capabilities. I may still do that.
